The relation that the educator has to specific entities of the world serves as both a model and entryway for the educand to develop similar relations. Emphasizing the educator’s direct relation to the world, to actions, ideals, understandings and knowledge—in short, to the world as a whole—highlights their power to select, simplify, adapt and otherwise prepare aspects of the world for the one being educated. In the classroom, selection, simplification and adaptation is an important part of the expertise that constitutes teaching. Very often, though, it is not the world itself that is thus prepared, but *representations* of selected objects and processes within it—in the form of pictures, games, exercises, books and toys. These are often effectively “pre-adapted” and “pre-simplified” to be more easily integrated in the educand-world relation—shaped precisely to improve this relation in some particular way: building blocks for children’s hands and coordination, or books for their interests and reading level. “We long ago accepted that the realm of schooling—and of childhood in general—“consists of a huge montage of images and representations which are not ‘the things themselves’ but instead ‘point out’ things and phenomena,” as Klaus Mollenhauer puts it (1983/2014, pp. 34–35).

The process of adapting and simplifying the world—or representations thereof—has been referred to as the *transposición didáctica*, *la transposition didactique* (Chevallard, 1997), and the *didaktische Reduktion* (Lehner, 2020). Focusing on knowledge, Chevallard asks: “Why is a *transposition didactique* needed?” “Because the didactic function of knowledge is different than [its] scholarly function,” he answers, “because there are two regimes of knowledge [didactic and expert] that are interrelated but not superimposable” (as quoted in Makassikis, 2017, p. 99). Again, an educator is someone *not* necessarily in possession of subject-matter expertise, but of an ability to transpose and thus bring aspects of the world more capably and sensitively into relation with the educand. The transposition from expert knowledge to didactic knowledge can occur in a range of ways: through the use of examples that cover a broad range of cases (e.g., a bean sprout for all plant life), by focusing on part of a larger whole (e.g., a passage from a book), and by making knowledge appealing (e.g., through pictures, activities, mnemonic rhymes, etc.). This process extends to the person of the educator themselves—in Arendt’s sense of fulfilling a broadly “representative” role—in modeling the relation to the world that the educator wants to achieve for the child.

Emphasizing the educator-educand relation: communication

If the relation between educator and educand is emphasized over the other two sides of the pedagogical triangle, then the didactic approach becomes broadly communicative. Here, the student’s relation to others and to the world is to be improved precisely via collaborative negotiations with others. It may involve, for example, Socratic dialog between teacher and student, or collaboration within student groups. Whether educational groups are understood as “communities of practice” or as Pestalozzi’s domestic family, these members are seen as having the potential to reciprocally guide and educate one another.

Emphasizing the educand-world relation: experience

Emphasizing the educand's relation to the world entails an experiential approach, one that encourages direct engagement with and relation to the phenomena being studied. Such "educative experiences" as Dewey noted, are doubly important: Experiential education occurs precisely *through* the educand-world relation while pedagogy itself simultaneously seeks to improve this relation: "Hence the central problem of an education based upon experience," Dewey observes, is to foster "the kind of present experiences that live fruitfully and creatively in subsequent experiences" (1938, pp. 27–28).

A didactic reduction or transposition is implied in communicative and experiential approaches as well as in "representational" didactics. In these cases, this reduction may mean that communication with others is directed in such a way as to be positive and cooperative rather than conflicted, or that experiences are deliberately cultivated that reward certain types of action, knowledge and awareness, and discourage others. Although Rousseau characterizes Emile's education as "negative" in nature, he places both communicative and experiential approaches at the center of his novel of education. And as Meirieu points out, Rousseau's "cunning" in this regard consists not only "in organizing his pedagogy around the 'interest of the child:' but by making sure, thanks to skillfully calculated situations, that 'what interests [Emile]' and 'what is in his interest' converge" (Meirieu, 1996, pp. 56–57). For example, while with his master, Emile loses his way in a forest, becomes hungry and begins to cry. Comforting Emile, his master reminds him of a recent lesson in astronomy and points out the direction of the shadows in the forest. Through this didactic transposition or reduction of the complexity of his environment, Emile is able to deduce the direction to the town and to find his way, crying: "Let's have lunch! ... Let's run fast! Astronomy is good for something!" (1762/1979, p. 181).

This incident also highlights a second important way that the educator can influence the educand-world relation, namely through the *redirection* of the educand's will and desire. In this case the master redirects Emile's hunger and despair into an effort to deduce the direction of the town—so that they might ultimately enjoy a warm meal (Fig. 3). In fact, Schleiermacher describes all educational efforts, all efforts at changing the educand's relation to the world, as either representing a kind of "support" or "counteraction" of the educand's actions and inclinations: One supports the efforts of the person being educated to try new things (in the world), to become generous, cooperative or knowledgeable, all while counteracting certain reactions, dependencies or habits seen as less desirable. In all of this, the educator works to elicit and encourage the educand's spontaneous "self-activity," activity on the educand's own initiative and with its own objectives.

Fig. 3 Rousseau shows how a difficult situation can be didactically transposed and Emile's desire pedagogically redirected (Public Domain).

Despite the techniques and approaches available to change the educand-world relation, those being educated are fundamentally free in relation to any and all attempts to influence them. All that education can do, as a result, is to continue to transpose aspects of the world and redirect the educand's desire—shaping a context through words and objects—to make such change more, rather than less, likely.

The educand-world relation—*Bildung* and the educational telos

Given that education seeks to improve the educand's relationship to the world, pedagogy must be able to tell what is good or better in this relationship and what is not. This has traditionally been done by positing an ideal state for this relation and by seeing it as the final ideal or *telos* of the educand's development, indeed all of education itself. Throughout the centuries, one image or another of an all-embracing ideal person has offered a unifying framework for this telos, from the Greek *areté* (i.e., virtue) (Jaeger, 1939–46), *kalokagathia* (from *kalós* & *agathós*, i.e., “beautiful” and “good”) (Marrou, 1956) and *enkýklios paideia* (i.e., general education), through to the Roman *humanitas* (i.e., the human as moral and cultivated being) or Christian Godlikeness. The term *Bildung* itself first emerged from the idea of humans developing in the image (*Bild*) of God, with such ideals gradually being secularized through notions of “reason” and *civilitéé*. Since the Renaissance, this ideal became increasingly more open and less defined, just as the old *scientia* (i.e., knowledge one could possess), became the new “science” (a procedure which someone undertakes regardless of what is ultimately to be known; Gadamer, 1972). As the idea of a specific, external educational human *telos* has gradually faded away—a process seen as intrinsic to modernity itself (Blumenberg, 1966/1983)—the acquisition of a canon, of “true” knowledge of the world and life, has been replaced by various modes of relating to the world, namely ones that are seen as reasonable, critical, autonomous and authentic.

For example, in his classic definition of *Bildung*, Wilhelm von Humboldt (2000) describes the process as one that is intrinsically open—as nothing less than “the ultimate task of our existence:”

This [task] can be fulfilled only by the linking of the self to the *world* to achieve the most general, most animated, and most *unrestrained interplay* [emphasis added]. This alone is the yardstick by which each branch of human knowledge can be judged. For in each case, the only true path is that on which the eye is able to follow steady progress toward the final goal (1794/2000: 58–59).

In addition to the emphasis it places on the educand-world relation (i.e., “unrestrained interplay”), Humboldt's definition of *Bildung* is also noteworthy for its continued relevance in Northern and Central European pedagogy today: “Globalization and neo-liberalism,” as one historian observes, have recently only lent increasing “international support to *Bildung* as a concept based on higher principles and moral values that are not easily reduced to simple measures” (Horlacher, 2016, p. 118). *Bildung* itself has come to represent “an unquantifiable excess value” (p. 3) that signals both the dignity of ongoing collective and individual struggle and advancement as well as the potential transformation of the self through the other (Koller, 2012).

Pedagogy as a “science”: theory and art

The idea that pedagogy is not just a collection of concerns, arrangements and values, but that it constitutes a comprehensive theoretical account of a distinct “art” or practice, emerged in Northern Germany in the late 18th century. This occurred through the development of a distinctly pedagogical or “educational science”—an *Erziehungswissenschaft*—with *Wissenschaft* referring to any domain of rigorous research. This research work began with the anthologizing of texts (e.g., of Comenius, Locke, Rousseau) by a group of Enlightenment educators known as the “philanthropists” (i.e., lovers of humanity) and with Ernst Christian Trapp's 1780 *Attempt at a Pedagogics* (pedagogics being a rigorous attempt at a pedagogical theory). A few decades later, F.D.E. Schleiermacher developed his own *Outline of the Art of Education* on the basis, as he was quoted above as saying, of the relation of the older and younger generations. Schleiermacher begins these lectures, however, by asking how the “entirely general statements” of theory could apply to the particularities of pedagogical practice that had for years—millennia, really—preceded it:

Originally, it was parents who educated, and as is commonly acknowledged, they did not do so following a “theory.” And it is true for every domain that can be called an art in the narrow sense of the word that practice always precedes theory. Therefore, it would be incorrect to say that practice gains its character and specificity only through theory. The dignity of practice exists independently from theory. Theory only makes practice more conscious. Schleiermacher (1826/2022, p. 44).

The dignity, integrity and value of practice arises not just because it came first, but because it is always addressing the unique configurations of educator, educand and world—moments that must by definition escape “entirely general” theoretical statements. Practice in this sense designates an “art,” a *τέχνη* or *techné*, a practical knowing and doing that is variable and context dependent. Theory, correspondingly, is not based on empirical and psychological findings that would dictate optimal arrangements or

“best practices” for all situations. “Theory,” as Schleiermacher has already noted, “makes practice more conscious.” It poses questions about the all-but unavoidable dilemmas of education—questions of the “relationship between the older and younger” generations, of moments of present and future, of tactful distance and supportive proximity in the experience of the child (Kenklies, 2012).

These questions and dilemmas are not posed to be answered once and for all or to tell educators exactly what to do; they do not indicate which course of action would be right or wrong, better or best. Instead, they are meant to engage educators in similar questioning, for example, regarding habitual solutions, fashionable prescriptions, actual actions and possible alternatives. Such dilemmas and reflections—whether analyzed in academic discourse or in terms of immediate educational engagement—are seen as constitutive of pedagogy as a “science.” Instead of giving answers, the point of such theory is to “attune” practice, as Schleiermacher’s contemporary in pedagogical theory, J.F. Herbart (1776–1841) maintained. Like Schleiermacher, Herbart also began one of his most famous lectures in pedagogy by reflecting on the opposition of theory and practice. Herbart saw this as an opposition that could be reconciled, specifically through the addition of pedagogical tact as a mediating element:

But for every theorist who puts his theory into practice in particular cases ... a link intermediate between theory and practice involuntarily inserts itself. By this I mean a certain *tact*, a quick judgment and decision that is not habitual and eternally uniform Based on continuous practice, there inevitably develops in humans a mode of action that is dependent on feeling but that only remotely relies on certainty of belief (1802/2022, p. 32).

Like Nohl after him, pedagogical tact for Herbart is a kind of enacted disposition that provides the educator with a certain distance and also proximity in relation to the educand. Again, as reflected in the work of later educationists—from Nohl to Arendt—the basis of such sensitive engagement in pedagogical practice is a matter of one’s stance, frame of mind or attitude. And improving one’s engagement, as Herbart makes clear, is first of all a matter of reflectively preparing and cultivating this stance or disposition precisely through theory or “science.”

by reflection, reasoning, inquiry—in short, by science—the educator must prepare not his future action in individual cases as much as *himself, his disposition*. He must prepare his *head as well as his heart* to correctly receive, perceive, feel, and judge the phenomena awaiting him and the situation in which he will be placed. If he has, in anticipation, indulged in extensive plans, the practical circumstances will mock him (emphases added 1802/2022, p. 33).

The topic of pedagogical tact has recently experienced a Renaissance both in the German and French languages, with Herbart’s (and others’) characterizations being updated for contemporary theory and practice. For example, Burghardt and Zirfas (2019) open their recent book-length examination of *Pedagogical Tact* by characterizing this tact as marking “a central perspective in the field of tension between determinacy and indeterminacy in education, *Bildung* and instruction” (p. 9). It is a tension, they add, “that simply cannot be converted into systematic ‘determinacy’ or empirical ‘univocality’” (p. 9).

Ways of knowing: continental pedagogy and curriculum studies

In defining pedagogy as both a theory and a practice, and in understanding the two as connected through a reflective and responsive disposition, Herbart, Schleiermacher and others also give effective definition to pedagogy as a *way of knowing*. On the one hand, it represents an art, a practical way of knowing—an attuned awareness or disposition—that may not even reach to the level of theoretical articulation; on the other hand, it is a way of reflecting, a particular perspective on life, even a “theory.” Together, pedagogical theory and practice constitute a way of knowing that combines emotion, feeling and commitment together with a more reflective, awareness—a “*besonnenes Bewusstsein*,” a considerate consciousness, as Schleiermacher puts it.

Indeed, the configuration of the pedagogical triangle itself can be said to represent a “theory” of pedagogy. But this is not one that stands or falls on the basis of statistical generalizability or empirical evidence (e.g., how many times this configuration can be traced in a given classroom). It instead represents a model that allows us to identify education “out there” in the world, both in a theoretical and practical sense. Processes, persons, objects and arrangements need no longer be labeled “educational” simply because they happen to be found in places known as “school,” “college” or the “classroom.” Instead, this theory provides educational thought and research with an intrinsically human set of phenomena that constitute a clearly-bounded set or an object for their investigations. It is a curious but telling fact that most English-language reference works that claim to cover “education” overall (including this one) conspicuously fail to provide either a definition of education, or—as suggested earlier—explicit definitions of “pedagogy” as well (Friesen, 2019, 2021). Not only does Continental Pedagogy define such terms and their interrelation, it also identifies a timeline of historical texts in which their meaning has been refined and reaffirmed. As they have been briefly reviewed above, these sources show that pedagogy is not a set of prescriptions for the classroom, but rather, a set of relations that can arise in the widest variety of contexts, both real and imaginary—from Plato’s cave through Rousseau’s natural tutelage to Humboldt’s *Bildung*. Such examples illustrate that pedagogy not only represents a way of generating questions and identifying dilemmas that are specifically pedagogical and educational, but also that it offers a specifically *pedagogical* way of understanding not just education, but the world in which it

arises. As Gert Biesta has said, it offers “a distinctively *educational* perspective on education” (2015, p. 15)—one that goes well beyond educational institutions and embraces the world of human relation, influence and intention as a whole. It holds out the promise—as a recent French translation of Herbart’s pedagogical works puts it—that pedagogical thought is able to speak to “the overall contexts of pedagogy,” contexts which have long been neglected “in the framework of particular specializations or disciplines” (2007, cover).

Significantly, Herbart himself wrote about the dangers of “the science of education ... being conquered and ruled from afar,” precisely by other sciences or disciplines. Herbart argued that “it would be better if the science of education remained as true as possible to its own *intrinsic conceptions* and cultivated more an *independent mode of thought*” (1806/1908, p. 83; emphases added). In addition to illustrating how education can indeed cultivate this independence, this article has also attempted to introduce a number of the “conceptions” that Herbart saw as “intrinsic”—words like *educand* (*Zögling, le élève, alumno*), *Bildung*, pedagogical tact, and *la didactique*. We have further extended this vocabulary with ideas and practices like representation, self-activity, *l’éducation négative*, and the didactic transposition or reduction. Meanwhile, in the case of English language education, we can say that the colonization of education by other disciplines that Herbart warned of is now complete: The dominance of the social and psychological sciences, together with elements of philosophy and critical theory, is now so total in education as to have rendered it simply a “field” of phenomena to be studied only from *other* disciplinary perspectives (see: Bellmann, 2014, p. 277).

Curriculum Studies—whether contemporary or traditional—can also be said to accept today’s understanding of education as a “field” to be addressed by managerial, critical and other types of disciplines and theories. In an age of managerialism and standardized testing, its aforementioned concern with institutional forms has given contemporary Curriculum Studies a focus on the “catastrophic,” even “fascistic” results of corporate, governmental and administrative instrumentalities (Pinar, 2019, p. 124). In this context, contemporary curriculum theory has advocated for possibilities of renewal, for a new conception of curriculum that would function “as a bridge between the social and subjective, connecting as it reconstructs both” (p. 124). The result is that curriculum itself would be “enacted as [a] complicated conversation,” something that unfolds among adults—and is “intensely historical, political, racial, gendered, phenomenological, autobiographical, esthetic, theological, and international” in its nature (Pinar et al., 1995, p. 124, p. 847).

In this light, the contributions that Continental Pedagogy could make in mutual dialog with Curriculum Studies are manifold: First, it provides a non-managerial, non-psychological but nonetheless *practical* account of the pedagogical. As a part of a personal relation situated in the world and aimed at the educand becoming “who they are,” Continental Pedagogy conceptualizes both pedagogical action and reflection in ways that are irreducible to measures of efficiency or outcomes. Unlike many diagrams of educational systems and processes that are ubiquitous today, the pedagogical triangle does not map out any educational inputs our outputs, or any mechanisms for optimization or value generation. This triangle—and the theory it implies—instead portrays pedagogy as an ongoing engagement that is above all ethical and relational. And even if this type of relation and action may be subject to conditions characterized by some as catastrophic or fascistic, Schleiermacher and Arendt’s analyses suggest that there would still inhere within them a dignity and humanity that exceeds political categorization.

Introduction

It has been argued for a long time that today's information- and knowledge-intensive society, together with changes in globalization and values, is changing the conditions for education and schooling. New knowledge flows where information is available to everyone, which means that the accepted answers to what is valuable to know and learn in school are no longer self-evident. At the same time, most countries have a long tradition of nationally and culturally institutionalized curricula that formulate and structure the schools' knowledge content and forms. How the established school subject structure is influenced by international discourses about lifelong learning or 21st-century transversal competencies is an open question (Anderson-Levitt and Gardinier, 2021). This chapter addresses the question of knowledge in curricula and introduces theories, concepts, and research on how different orientations of the view of knowledge and their respective foundations in different traditions, such as scientific rationalism, social efficiency, and learning-centered and social reconstruction, have consequences for the schools' knowledge content and the organization of teaching in schools.

Three dimensions are crucial in dealing with these issues—the institutional, the programmatic, and the textual curriculum—which accordingly make up the outline of the text. First, after framing the general topic, the history of the curriculum structure (i.e., the institutional curriculum) is addressed. Usually, the so-called cultural grammar of schooling provides background assumptions that are taken for granted, such as the structure of the school subjects. However, knowledge traditions do change. Special attention is paid to research on how the view of knowledge can be related to different competing curriculum ideologies and displacements over time. Second, the programmatic curriculum is addressed, which includes the formal regulation of national curriculum making. With reference to the Swedish case of curriculum change, the features of the curriculum as a program are outlined. As many countries today apply different forms of knowledge in their curricula, for example, knowledge and competencies, the case study of Sweden highlights the international trend on curriculum standardization and convergence present in many countries worldwide. Third, the textual curriculum, how transversal key competencies are related to the curriculum as text, is tackled in the final part of this chapter and triggers induces the concluding discussion on theorizing the knowledge question of contemporary schooling.

Framing the issue of knowledge traditions and curriculum structure

Let us start with the most fundamental questions about curricula. What should be counted as knowledge? What selection of knowledge, values, and so on, should be made in compulsory curricula and syllabi? This is not a technical issue but one that involves epistemic and ideological, as well as cultural and political dimensions. When we discuss knowledge in curricula, a number of culturally, socially, and politically established premises need to be considered. It is neither a given that we can talk about *one* legacy of knowledge to be passed on from one generation to the next, nor is the institutionalized subject structure an unchanging entity.

Currently, we need to take a more open and pluralistic approach to different perspectives and contexts for the knowledge, as well as for the students' varied backgrounds. Interestingly, an opposite trend drives toward curriculum standardization in increasing comparability across nations and educational systems.

All societies are based on socialization and educational processes, where schools play an important role, but learning is also shaped by our own activities and close social interactions. Civic education enables participation in democracy and social life. However, there is not one but several different ideals and traditions around such socialization and educational processes. *Selective tradition* is a concept used in curriculum theorizing to show how schools knowledge content (e.g., in the form of a subject's predominantly taken-for-granted assumptions about what constitutes knowledge), how learning takes place, and what kind of teaching should be conducted, are based on certain traded perceptions (Englund, 2005). In both theory and practice, the curricula contain a normative dimension regarding knowledge selection, classification, and framing, based on human knowledge archives (Sundberg, 2021). Various forms of cultural canons, collective memories, social imaginaries, and political narratives form a horizon for all work with and decisions on curricula and syllabi in transnational, national, and local arenas.

In line with a linguistic turn in social theory and curriculum analysis, as demonstrated in the following text, several hidden premises have been placed in the spotlight. This applies to questions about why (the legitimacy of the content), what (the content and its organization), how the content is communicated in the school's teaching, when new content should be introduced (progression), and who is mandated to decide on these priorities. On one hand, the aims, goals, content, and forms of education and schools exist in the context of a constant struggle among different perceptions of what knowledge is, how teaching should be organized, what should be counted as valid knowledge, and which learning should be rewarded, historically configured by dominant curriculum ideologies (Englund et al., 2012). On the other hand, there is always a hidden dimension to culturally established norms that affect the design and content of curricula, which the sociological turn of education has clarified since the 1970s through the concept of the *hidden curriculum* (Jackson, 1968).

The cultural reproduction explanation model that emerged with the *new sociology of education* in the 1970s (i.e., the official school knowledge reproduces the dominant class power patterns in society) has been challenged and succinctly replaced by more dynamic models explaining the structure and knowledge content of schools. Along with the linguistic and discursive turn in social theory, the curriculum concerns not only the dominant *power over ideas* (i.e., the imposition of ideas and ideological reproductive gatekeeping) but also the *power in ideas* and the *power through ideas* (i.e., the ideational capacities, individual and collective, to influence normative and cognitive beliefs in communicative discourses) (Carstensen and Schmidt, 2016). Endogenous and exogenous drivers of change, continuities, and the discontinuous discursive controversies reconfigure the curriculum in the nexus of scientific, public and political, administrative, and professional arenas. However, the latent or background ideas that structure the forms and knowledge content of schools are highly formative.

Such an often-hidden dimension of schools' substantive organization concerns the division of subject domains into theoretical and practical subjects that can be traced back to Aristotle. It is a historically established hierarchical division that contributes with a kind of cognitive and institutional architecture (Deng and Luke, 2008). Tyack and Cuban call this phenomenon the cultural grammar of schooling for the knowledge content that remains strong in universities as well as schools in the Western world (1995). However, it is not a given, and in an information- and knowledge-intensive society, the ecologies and cycles of knowledge change, as we will see (later on in this chapter) reflected in the case of Swedish curriculum policymaking.

Premises for knowledge divisions in curricula

To understand the knowledge dimension of curricula, we need to, on one hand, address the discursive dimension and, on the other hand, acknowledge that the structure of knowledge is partly about deep intellectual epistemological traditions that can be traced to ancient Greeks, from Socrates (469–399 BC) and Plato (429–348 BC) to Aristotle (384–322 BC) and Alexander the Great (356–323 BC), to mention some key figures. Often, since then, construed by philosophers as an epistemological problem, the structure of knowledge invokes multiple ways of knowing, such as experimentation, empiricism, revelation, authority, rationality, intuition, meditation, and embodied knowing. In the classical curriculum, trivium and quadrivium comprised the basic architecture of the knowledge content for schooling. The word *trivium* comes from Latin and means the place where three roads meet. Originally, these consisted of grammar, rhetoric, and dialectics (Hamilton and Zufiaurre, 2013). In higher education, these were later complemented with four domains of knowledge (*quadrivium*): arithmetic (mathematics), geometry, music, and astronomy.

The modern curriculum conformed to tradition by retaining school subjects as the building blocks of the curriculum—although, to be sure, the modern subjects were not necessarily the same subjects or in the same form as those in the classical curriculum (Lundgren, 1984). Curriculum scholars have helpfully clarified such transformations. In the 1970s, Hirst (1974) extended R.S. Peters' (1919–2011) work in the analytic philosophy of education to address the issue of how the structures differed in various domains of knowledge (the disciplines). Hirst (1974) identified four characteristics of structures, each of which differed across knowledge domains. The core concepts varied across disciplines, as did the logical relations among them and the tests against experience, and the different forms of knowledge have developed unique techniques and skills. Based on these differences in their structures, Hirst (1974) identified seven forms of knowledge or disciplines: (1) mathematics, (2) physical sciences, (3) human sciences, (4) history, (5) religion, (6) literature, and (7) the fine arts.

Indeed, the realist stance that Hirst (1974) represents (i.e., school subjects mirror or correspond to basic objective realities) has been challenged. Joseph Schwab (1909–1988) called for an alternative position in structuring knowledge in the curriculum using

Deweyan lenses and by drawing on Aristotle's tripartite treatment of inquiry (theoretical, practical, and productive). He called for pragmatic discarding of moribund stable theoretical inquiry that focused on overgeneralized problems and empirical methods that sought lawlike principles of education. Instead, he advocated replacing it with the fluid, practical inquiry that would look for situational insights to interact with and remediate specific problems by engaging in productive eclectic arts of matching and tailoring theories to situational needs. Thereby, curriculum scholars should create a precedent to anticipate and generate alternative practices in order to enhance decision and action as social realities change and as we face new social challenges that confront education (Schwab, 1969, 1978).

The institutional curriculum: three basic knowledge concepts

There are profound traditions regarding the basic structures for the organization of schools' knowledge content; it is not a simple matter of either objective and enduring subject structures or problem-based and situational inquiry. In Deng and Luke's (2008) more recent thorough review of subject classifications in education and schools, they have identified three basic knowledge concepts (ideal types) that have structured schools' subject content worldwide and historically over time. (1) A disciplinary conception of knowledge constructs it in terms of canonical academic knowledge that embraces different traditions but revolves around on facts, concepts, and ideas that have been formulated and tested in scientific discourses over time. Here, pieces of reality are arranged and rationalized in hierarchies, categories, and taxonomies that systematically arrange different domains of knowledge. (2) A practical knowledge concept is action oriented toward certain practitioners and focuses on the use of knowledge around practical and socio-cultural problems. It can be about a set of procedures for successfully managing activities, as well as about considering different courses of action (metacognitive strategies) and embodied learning (compare, e.g., Aristotle's concept of *phronesis* with Pierre Bourdieu's concept of the logic of practice). (3) An experience-based knowledge concept focuses on social and cognitive elements in understanding and making phenomena in the everyday environment understandable and manageable. Here, the focus is on knowledge in everyday life and situations between the actor and his or her environment and between the subject and the object. From a pragmatic perspective (as in John Dewey's work), knowledge entails an ongoing construction of meaning that social actors create based on bio-social environments where both linguistic and semiotic interactions, as well as material artifacts and resources, are used for common dealings (Dewey, 1899/2009).

The different knowledge traditions have—to varying degrees—delivered premises for curricula. Most traditional definitions of knowledge for curricula tend to emphasize the former, cognitive, and fact-oriented subject or disciplinary conception. It is an uncommon procedure—although recommendable—that the question of knowledge and curriculum content is made part of public discourse. In connection with the work on the curriculum reforms in the 1990s in Sweden, a discussion was held on precisely the different dimensions of the concept of knowledge. The four forms of knowledge (facts, understanding, skills, and judgment) became ways to create space for different conceptions of knowledge, rather than just the epistemological and disciplinary one (Carlgren, 2009). However, the former, theoretical disciplinary conception has historically been dominant as a premise in the public understanding of and organizing principles for the construction of curricula.

Nonetheless, current changes in the curriculum landscape challenge such clear-cut knowledge divisions. In the discussions among curriculum researchers, the distinctions between cognitive and non-cognitive, theoretical and practical, or formal and informal education comprise the manipulation of those symbolic resources (words, numbers, pictures, etc.), which point to external demands for skills in changing labor markets, challenged democracies, cultural pluralism, and so on. Competency-based education and skill-based knowledge emphasize socio-cognitive and procedural knowledge (rather than cognition and declarative knowledge), along with the active inquiry of the learning in defining the learning objects. A purely skill-based competency curriculum that underpins an international comparative system of testing, such as the Program for International Student Assessment (PISA) (Organization for Economic Co-operation and Development [OECD], 2019), would mistakenly reject this distinction and its designation as an epistemic activity. Superficially, the PISA literacy concept attempts to take the critique of the separation of formal and informal education into account by stressing the importance of basic competencies to meet challenges for learning in real-world situations. However, there are different ways in which cross-disciplinary competencies are added on, are integrated, or transform subject structures of national curriculum frameworks (Nordin and Sundberg, 2021).

Distinguishing between knowledge of how to do something (procedural, practical, and experiential) and knowledge of something (declarative and disciplinary) is important, but both are, in essence, knowledge-making activities. For example, dispositional knowledge is one concept that transcends such a division and refers to relatively stable habits of mind and body, sensitivities to the occasion, and participation repertoires. The three types of knowledge thus have different forms in their original states and as a result, various pedagogical structures and expressive or performative modes. They can only be assessed functionally in relation to their different internal relations, that is, there should be diverse ways of assessing or evaluating them. However, as argued by Bellmann (2010), the PISA literacy concept as functional for the real-life situations outside schools borrows from the language of progressivism; still, there are potential contradictions in aligning generic skills with disciplinary school knowledge.

Four curriculum ideologies and different views of knowledge in modern schooling

To understand how curriculum content and knowledge are changing, a realistic account of the various ideological forces at play is necessary (Sundberg, 2021), although this dimension usually goes under the radar of policymakers. In international curriculum

research, four different dominant historical curriculum orientations are identified, linked to the emergence of modern schooling (see, e.g., Kelly, 2009; Schiro, 2013). They represent various systems of ideas, culturally established assumptions and ideas, which in diverse ways, form the basis for curriculum constructions and knowledge conceptualizations. Let us look at the view of knowledge within these.

View of knowledge in a scientifically rational curriculum ideology

This orientation focuses on and emphasizes the transfer of disciplinary subject knowledge in order to develop the learner's intellectual capacities and reproduce a cultural tradition based on such basic knowledge and common frames of reference. Academic disciplines here constitute authoritative resources through which the school subjects also gain their legitimacy. Essentially, it is a curriculum of knowledge, techniques, and ways of knowing that is passed on. Many curricula have strongly relied on a traditional (essentialistic) subject structure, what has been called *the cognitive architecture of modern curricula*. A content-oriented curriculum usually provides concrete instructions for the content that students must encounter in the teaching, in terms of subject matter and work and teaching methods. The emphasis is on the substance to be conveyed. In some countries, canon lists are also made, indicating cultural frames of reference in different areas. An underlying assumption is that the content conveyed by the teaching is also what the students learn (i.e., the impact premise). In the international curriculum discourse of the 1990s, this disciplinary notion of school knowledge was challenged as more learner-centered ideas of active participating became influential, with the so-called first wave of competence-based curricula (Sundberg, 2021).

View of knowledge in learner-centered curriculum ideology

A curriculum orientation toward a liberal humanistic direction is driven by the focus on the individual's learning in what should constitute central school knowledge content. The school should foster personal development, self-realization, innovation, and creativity. Disciplinary knowledge is relevant as long as it contributes to the development process and self-realization of the individual. A curriculum can consequently contain a wide repertoire of knowledge, experiences, and resources that can have a liberating effect. Historically, pedagogical progressivism (and reform pedagogy) has been a movement against this type of curriculum construction. In recent international curriculum development, there are also examples of how this ideology has driven competency-oriented curricula (Englund, 1996). In recent decades, many countries have focused on identifying and systematizing competency goals for students (Anderson-Levitt and Gardinier, 2021). Different kinds of generic abilities are formulated, which, among other things, are about learning to master different practices and problems by distinguishing, assessing, resolving real-life issues, and so on. They are usually designed according to goal and result management principles, something that content- and process-oriented curricula do not have to be and have not been. In many countries, including Sweden, this curriculum ideology was highly influential in the restructuring of curricula and syllabi in the 1990s. At the same, the pressures for education efficiency and measurable outcomes framed the implementation and enactment of the competency-based curriculum in practice.

View of knowledge in social efficiency as curriculum ideology

This curriculum orientation stresses the importance of equipping prospective citizens with the necessary skills, knowledge, and cultural capital for economic and societal productivity and growth. The questions about curricula are related in this way to questions about strengthening human capital. The benefit, that is, the functional value of the knowledge, becomes central to the strengthening. Subject knowledge is linked in this way to the various skills required in working life. In a post-industrial society, particularly those generic competencies that can be used in different spheres (social and economic) have formally and informally come to the fore.

The result-oriented curriculum, which is an expression of this curriculum ideology, is usually a combination of a content-based, a process-oriented, or a competence-focused curriculum. However, the result-oriented curriculum is designed so that it also states and specifies what the student should have learned, relating to different specific minimum levels based on the so-called performance standards (Kelly, 2009). By linking content requirement levels (referred to as alignment in the research literature) with assessment and grading criteria, results in the curriculum and in the student's learning are focused on in a distinctive way (Meyer and Benavot, 2013). In many countries, curriculum reform gradually became more result-oriented as the pressures on the competitiveness of educational systems in the new knowledge economy pushed for efficiency, according to international performance indicators.

View of knowledge in social reconstruction as curriculum ideology

This conception emphasizes the sociocultural and sociopolitical context rather than the individual in curriculum decisions. Education and schooling are important tools in a societal reform toward increased equality, justice, and equity. In accordance with this orientation, a curriculum also needs to contain a study of societal contexts, issues, and possible futures to enable the individual to develop one's own positions and future paths. Subject knowledge then becomes a set of more diverse activities that contribute to meaningful learning experiences for one's own agency. Different value dimensions become central for the curricula constructors and developers to consider. Process-oriented curricula are focused more on students' learning experiences and learning processes and less on predetermined content. They emphasize characteristics of the development of students' learning and thus also cover skills and attitudes. The curriculum is a means of trying to control the various processes involved in education and teaching. Content and

methods are only aids to achieve desirable development processes at the individual, the group, or the societal level. Thus, the focus is on societal challenges, working methods, and cognitive tools to broaden students' experiences and insights, rather than on subjects or a given body of knowledge. Despite its historically strong influences in the curriculum reforms in the Nordic countries, this curriculum ideology has clearly become marginalized over the last decades.

The programmatic curriculum

Regarding the history of curricula, there is a need to acknowledge the differences between the North Continental and the Anglo-Saxon curriculum traditions, as they have largely structured how curricula have been constructed (Gundem and Hopmann, 1998). The Continental tradition has a history dating back to the 17th century and Johann Amos Comenius. He was behind what has become the prototype for modern curricula, *Didactica Magna* (1657/1999). Some distinctive features of this entire North Continental curriculum and *Didaktik* tradition are that they have been philosophically oriented and the theorizing have built on conceptual models, with a focus on schools' social mission and knowledge content. The Anglo-Saxon curriculum tradition does not have the same long history. For example, in the USA and England, curriculum issues have to a greater extent been practical and empirical. Taken together, however, both traditions have also been based on some common starting points. Hopmann (1999) stresses that the underlying premises are based on the following premises:

1. The required knowledge, attitudes, and abilities are known and can be specified in curricula.
2. What is specified can also be taught.
3. What can be learned through teaching (i.e., its actual outcome) also corresponds to the desired outcome.

Hopmann describes them, respectively, as the *planning*, *learning*, and *impact* premises for curricula (1999). However, none of these can be secured in a school's history as empirically substantiated. They are assumptions that must be made but whose uncertainties are always in play. They represent a kind of hidden action theory that governs the work with curricula. They are general and deeply institutionalized but at the same time, raise questions about the power to define the school's knowledge content and about political, expert-based, and professional control in curriculum-making processes at various levels and arenas. On one hand, the democratic premise says that there should ultimately be democratic decision making behind the curriculum, based on scientific expertise. On the other hand, a *living curriculum* presupposes that professionals perceive ownership of the taught curriculum.

However, the space for professional curriculum making is restricted and framed as workable organizational frameworks for the delivery of schooling. The programmatic curriculum consists of the regulation of formalized curriculum making and national political governance of the goals and content of the educational system (Westbury, 2008) as part of the political jurisdiction and as an instrument for steering the school system. The curriculum as part of a steering program does not only consist of specific document goals, content specifications, assessment criteria, and so on, but it also includes the interrelated programs of in-service education, textbooks, guidelines, the assessment system, and so on. The programmatic curriculum include "routine educational and administrative activity of many ministries and boards of education as they support and ratify ongoing revisions and changes in subject areas and courses of study" (Sivesind and Westbury, 2016, p. 744).

The programmification of the curriculum thus results in specific configurations of content selection, as well as emphasizes and prioritizes what, how, and when content should be taught. Subjects are building blocks for the routinization of the inner work of schools. The administration of the school system and the management in the schools are organized around the subject structures. When comparative scholars refer to an ongoing curriculum convergence globally, it concerns these textual and programmatic dimensions of the curriculum. In many educational systems across the world, a kind of curriculum programmification is observed as loosely coupled systems are replaced by an effort to align goals and content according to performance standards and tests. In some countries, mainly Anglo-Saxon, this results in a highly prescriptive, detailed, and scripted teacher-proof curriculum, with guidelines for teachers to follow in order to climb in the rankings of international achievements tests such as PISA.

Curriculum standardization

Although the curriculum is a contested issue at the very center of education and schools today, a slow global convergence is discernible, which mostly concerns the programmatic and technical aspects of the curriculum. Meyer et al. (1992) refer to the modern curriculum as a tamed and professionalized curriculum. Global standardization of school subjects can be identified over the last 100 years. This does not merely involve curriculum rhetoric and terminological categories. Comparative analysis reveals increasing convergence, homogeneity, and standardization in curriculum systems, policy programs, and assessment systems (Meyer and Rowan, 2006). While a general common-sense understanding and a general definition of education standards are the expected levels of achievement for all children of a particular age, it is vital to place them in the historical context of curriculum making in order to understand the emergence of such standards in education. Kliebard (2004) specifically refers to scientific curriculum making and the rise of social efficiency as an educational ideal in the early decades of the 20th century. The allure of having a clear and coherent system for teaching, learning, and assessment is closely related to the scientific outlook. "Standards are presented as a rational and scientific way of making and controlling a curriculum" (Waldow, 2015, p. 59).

Standards are usually represented as technical objects in contemporary educational discourses (i.e., fixed, stable, and universal). However, a closer critical investigation indicates the contested nature and ambiguities inherent in standardization processes. First, conceptualizing standards as epistemic objects means that they are defined by a struggle among different power alliances (i.e., standards are carriers of implicit normativity). Second, presenting them in a uniform way across contexts underestimates the dynamics of standardization by different actors and institutions in translating them into norms and actions (Brunsson and Jacobsson, 2000). Broadly speaking, regarding education, *content standards* include prescribed goals and curriculum knowledge (input), and *performance standards* define levels of student achievement (outcomes). In this chapter, we further explore the gradual shift in curriculum discourses, from content to performance standards, that has occurred from the late 1960s to the present day. In general terms, standardization can be defined as a process of building uniformities in time and space through agreed rules (Bowker and Star, 1999).

Examining modern educational systems today shows that standards proliferate and are particularly relevant when thinking about regulating curricula beyond national boundaries (Djelic and Sahlin-Andersson, 2006). In a broad sense, standards can be defined as constituting a particular type of rules—usually voluntary rules that are explicitly formulated, pertaining to a wide range of actors (individuals or organizations)—that are recommended to be adopted in order to allow comparisons across contexts. Indeed, a variety of organizations are involved in developing, sustaining, and implementing curriculum standards (content and performance), including, but not limited to, standard makers, adopters, monitoring and certification agencies, and the larger public. Standards and standardization are often addressed as part of the broader discussion on organizational regulation. Regulation involves creating and propagating more or less explicit rules and thus fosters the formation of social order. Thus, studying standards allows us to consider both the *demand side* of order (i.e., how organizations and individuals are affected by organizing efforts) and the *supply side* (i.e., how organizing elements are produced).

Despite their pervasiveness and significance in modern life, standards have received comparatively little serious attention from curriculum researchers. It is only over the last few years when researchers started to systematically explore the social dynamics of standardization in education—the dynamics involved in standard development, standard setting, standard compliance, and standard enforcement. An example is the case of key competencies and their associated performance indicators promoted by the OECD (2019). While standards are often associated with rigidity and formalism, a closer study reveals standardization as a highly dynamic process involving multiple actors (individuals and organizations) and often fostering creativity and innovation on the side of both standard setters and followers. Curriculum scholars have lately directed attention to how actors (scientists, experts, bureaucrats, etc.) deploy techniques to mobilize other actors and to govern at a distance, beyond local spaces, and via calculative devices and translation processes into new patterns of actions (Bowker and Star, 1999; Brunsson and Jacobsson, 2000).

One main topic among researchers and policymakers in the field of curriculum and instruction concerns such processes of standardization and its benefits and risks. Curriculum coherence and curriculum alignment are central concepts in addressing not only the external but also the internal factors involved in curriculum standardization. The notion of curriculum coherence highlights the links between curriculum aims and content, teaching practices, and assessment. Some findings have suggested that a high level of curriculum coherence is associated with high-performing systems (e.g., Oates, 2011). Curriculum alignment refers to the process of ensuring consistency between the intended curriculum, as stated in its aims and objectives, and different learning and assessment activities in classrooms. Nonetheless, many studies have shown that curriculum content (whether we refer here to its essence, its legitimacy, or its genealogy) is contested and thus requires choices to be made among different formulations, conceptions, and arrangements (Englund, 1996; Sundberg and Wahlström, 2012). In turn, this has implications for the types of pedagogy that can be employed and the types of evaluative procedures that should be adopted. The Swedish case of the recontextualization of its curriculum and the enactment by teachers and schools shows that this is far from a univocal linear process of implementation.

Knowledge and curriculum change: the case of Sweden

Sweden is a good example of a country that is in the middle of two fundamentally different ways of governing with curricula, in the field of tension that Hopmann (2003, p. 460) has described as “content and process control” and “outcome and product control.” Sweden has had strong cultural and educational links to the North Continental European tradition, especially the German Didaktik tradition. This is characterized by content and process control, a licensing model for teachers, professional self-control, and self-evaluation (Sivesind et al., 2012). The political leadership has trusted that the professionals will handle and carry out their assignments internally. However, a new type of management philosophy of more product control has quickly gained ground in recent decades. It is characterized by a focus on outcomes and efficiency and is largely based on an Anglo-Saxon curriculum tradition (Gundem and Hopmann, 1998).

On a general level, the curriculum as a system of ideas (i.e., the institutional curriculum) has also been pushed into the background under the international pressures of curriculum standardization, along with an Anglo-Saxon framing, leaving the knowledge heritage unexamined. Instead, it is the curriculum as a program that has come to the fore in contemporary educational policy in Sweden, as well as in many other countries. It is about building a goal management system that is aligned and operationally

efficient. A look inside the work with curricula makes it clear that there are far from rational and well-planned processes behind new curricula, without them also being governed by different pragmatic and contextual conditions. In an important research study from within the work with the curricula in the early 1990s, the scholar Ingrid Carlgren described the curriculum work as a form of practical problem solving rather than a rational deliberation on governing principles and ideologies:

The curriculum proposals (that were considered within the 1993 curriculum commission) did not come about as compromises in relation to substantive and ideological discussions, but from an interaction between the factors framing the process, incidental events, and practical considerations. Part of understanding curriculum change is, therefore, to understand what problems there are to solve (1995, p. 412).

In research on curriculum work at the system level, it is now well established that there is a categorical simplification of the complex task involved in constructing a curriculum. An administrative simplification reduces different perspectives and discourses about a school's mission, subject content, and forms. Haft and Hopmann (1990, p. 25) have introduced the term "compartmentalization" for such a simplification. It is then usually a matter of adjusting within an existing system rather than changing the whole curriculum with a new one, which could threaten its legitimacy and stability. The work of organizing knowledge for curricula thus includes several different activities and processes at different levels. At a more societal level, there are societal and cultural ideologies and symbols, politics and organized interest groups, various organizational and political structures and processes, as well as local understandings and practices. Research shows that given the complexity of curriculum issues and ideological value loads, they are often reduced to technical and practical problem solving based on presumed premises (Westbury, 2008).

Framing the question of knowledge in the curriculum

The curriculum's view of knowledge has in many respects been strongly embedded in cultural traditions (i.e., it has been implicit). In connection with the radical Swedish school reforms of the 1990s, the concept of knowledge became more explicit, discussed, and re-thought. The directives for the Curriculum Committee stated that its work should be formulated on the basis of a view of knowledge that "shall rest on current research on knowledge and learning," that is, not on traditions and common sense (Curriculum Committee, 1994, p. 7; see also Carlgren, 1995). The idea was that knowledge and the schools' subject content could no longer be taken for granted but that the knowledge issues had to be dealt with by the schools' actors, not least the teachers themselves. Instead of a centrally prescribed view of knowledge, it was thought and required that at the local level, there would be conversations about different types of knowledge and how they would relate to one another and to each school's goals. The report *School for Education* (Curriculum Committee, 1994) emphasizes that the pedagogical professionals should be assigned the responsibility for developing a reflexive view on knowledge, learning, and teaching on which the activities are based, that is, stressing the continuity of the historically established licensing model and division of labor between politicians and education professionals. It is "the interplay between the teachers' theoretical ideas and the practical design of the activities that should be the basis for an increasingly reflected practice" (Curriculum Committee, 1994, p. 62).

According to the Curriculum Committee (1994), the previously implicit normative notions of how the schools' knowledge content and forms should be structured would be replaced by explicit knowledge discussions for which the schools themselves were responsible based on the various contextual conditions. The goals in the curricula would not govern directly but indirectly through teachers' interpretations and reflections. At the same time as the so-called participatory goal management opened up for extensive professional decision making on curriculum issues, the management also became driven by goals and results. The previous rule management that prescribed the schools' subject content and organization would be replaced by an outcome control. The state formulated an assignment, and the schools were expected to deliver the expected results. The licensing model of professional curriculum making was thereby accompanied with a new form of contract to deliver according to the prescribed performance indicators.

Competing views of knowledge in the Swedish curriculum discourses

The Swedish (and Nordic) curricula and knowledge traditions constitute an interesting case internationally. The Swedish school has been part of the model of the modern welfare state since the 1950–1960s. It has been founded on a political premise of redistribution. Within the framework of a common school, the school must function to compensate for different life opportunities. Concepts such as a school for all, equality, and diversity set certain standards for teaching and learning. They are also anchored in philosophical and moral ideas about the purpose and meaning of school and teaching, ideologically related to social reconstructionism. Altogether, since the 1960s, they have provided certain frames of reference or background understandings among various curriculum stakeholders when new curricula have to be produced (Wahlström and Sundberg, 2017).

Curricula and syllabi are always based on certain notions of knowledge and learning, something that can be formulated in the different types of curriculum ideologies. The question of what view of knowledge lies behind a curriculum construction has always been important at the same time as it has received varying degrees of attention and debate. It is not only about what is to be counted as important knowledge but also about the nature and significance of the knowledge for teaching and learning. When we discuss the view of knowledge in curricula, both explicit formulations in the governing documents (curricula, syllabi, commentary materials,

advice and guidelines, grading criteria, etc.) and the implicit, background ideas and assumptions should be included. For example, a scientifically rational curriculum ideology was a basic feature of the welfare model and the systemic reforms in the 1950s and the 1960s in Sweden. Gradually, it became an institutionalized background assumption in curriculum discourses until the 1990s.

However, throughout the 20th century, a traditional organization, in the sense of the teacher-centered communication of schools' subject content based on a scientifically rational principle and an essentialist curriculum ideology, had been challenged from various quarters. Not least, Ellen Key (1900/1996) contributed in Sweden with the *Century of the Child* to direct criticism at superficial factual knowledge transfer and the one-sided division of subjects and placed the learning student's entire development in the center instead. A traditionalist and essentialist versus a progressivist and learner-centered view of knowledge has taken opposite sides in an educational policy field of tensions. The dichotomies between teacher- and learner-centered pedagogies and between teacher control and pupil autonomy have impeded attempts to understand and address complex educational problems and have thwarted productive discussions among policymakers, researchers, professionals, and the public. The tensions were accentuated when competency-based curricula became a central theme of the curriculum discourse of the 1990s in Sweden, which was partly backed up by historical-background assumptions of a state or administrative progressivism, along with a learner-centered curriculum ideology.

The textual curriculum: formulating the official view of knowledge in Sweden

Instead of prescribing a certain view of knowledge from national educational agencies, the concept of knowledge began to be problematized and discussed in the national curriculum discourse of the 1990s. Not least, knowledge acquisition in terms of learning participation became a starting point for the discussions (instead of learning as memorizing). In line with the critique of Piaget and individual constructivism, the reintroduction of Vygotsky and the Russian cultural-historical theory formation came to form an important foundation (Adolfsson, 2013). Here was a critical point toward traditional knowledge assumptions, technical rationality, as well as dualisms that characterized the view of knowledge in curricula: thought-action, cognitive-social, empirical-normative, practical-theoretical, and so on. A traditional view of knowledge as fixed knowledge to be transferred from teachers to students in a given order and pace was challenged from several different directions, such as pragmatism, sociocultural theory, and phenomenographic research, with the context of knowledge and different values emphasized instead (Carlgren et al., 2009). Carlgren (2009, p. 20) summarizes the view of knowledge in the new curriculum in three categories, as follows:

The basis of knowledge

- The knowledge is constructed by people in certain contexts for certain purposes (i.e., it is intentional, contextual, and functional in nature).
- The knowledge is carried by humans but is also found in cultural artifacts (texts, tools, and languages).

The form of knowledge

- The knowledge is expressed in the form of facts, understanding, skills, and familiarity, which correspond to knowledge, such as information, practice, interpretation, and judgment.

The content of knowledge

- School subjects are not formulated primarily in terms of material properties but as subject-specific qualities (expressed in the aim of striving for and the basis for assessment).

Such a view of knowledge as formulated here means that clear boundaries between theoretical and practical subjects have become blurred. All subjects are assumed to contain both theoretical and practical forms of knowledge. The hierarchy from theoretical to practical and down to less valuable subjects is also dissolved, as is the hierarchy spanning the four forms of knowledge. Instead, they are perceived as forming different but necessary aspects of knowledge. Formulations such as knowledge and skills were removed from national curricula and syllabi, as the concept of knowledge also contains skills. The view of knowledge expressed in the curricula from 1994 onward is also invoked to apply in the follow-up from 2011 and the present curriculum reform of 2022 (Official Swedish Government Report, 2007; Swedish National Agency for Education [NAE], 2022, 2011). However, the questions that arise are to what extent this view of knowledge is the dominant one in today's curriculum discourse, and what impact it has had on the implementation of the curriculum reform. Empirical research has shown that a traditional subject-centered view of knowledge, in combination with the instrumental values of knowledge, has become dominant (Wahlström and Sundberg, 2017), which has also been reinforced by the pressures on the competitiveness of educational systems pushed for efficiency, according to international performance indicators. The case of Sweden concerning the knowledge question in the curriculum makes it clear that institutionalized background ideas and subject structures provide a grammar of schooling that is difficult to change.

Curriculum theorizing on the knowledge question

Internationally, there is an intensive discussion on the question of knowledge in the field of curriculum theory (Wyse et al., 2015). Young (2008), in particular, has taken up a new discussion on curriculum knowledge over the last decade. In a general analysis of how the knowledge economy is about the conditions for education and schools, he believes that the schools' knowledge content has

been subordinated to various external objectives regarding productivity, growth, employability, and so on. Qualification and employability in emerging labor markets have created a management mindset around curricula centered on various performance indicators. His critique is that standardization of performance criteria and generic skills denies students access to what the disciplines can provide in the form of powerful knowledge (access to powerful knowledge). This social realist position thus criticizes the curriculum ideology of social efficiency from within the scientifically rational curriculum ideology by stressing disciplinary knowledge as an end in itself (intrinsic value), not as a means for economic and societal productivity (extrinsic value).

Scott (2014) discusses the question of knowledge in curricula based on what kind of knowledge is sought, the central principles of how it should be formed, and how it can be legitimized. He believes that these are necessary—although vast and difficult—issues to work with around the curricula. Here, consensus and hidden premises are major and difficult obstacles. He advocates a visualization and an identification of different curriculum ideologies that work so that hidden premises become the subject of discussion and deliberation. In what he calls essentialism (foundationalism), instrumentalism, and pragmatism, there are critical aspects that need to be considered to be able to construct solid and sustainable curricula. An essentialist (scientifically rational) conception can become too internally preoccupied, the instrumental conception can become too focused on external goals, and a pragmatic conception can be problematic due to its preoccupation with social goals.

Recent curriculum research clearly indicates that contemporary curriculum changes must be analyzed on the basis of the global processes driven by powerful transnational actors and national and local contexts with their historical, cultural, and political conditions in order to avoid simplified and/or overestimated analyses (Nordin and Sundberg, 2016; Sundberg and Wahlström, 2012). In recent decades, transnational policy actors have become important premise suppliers for curriculum work, as education and economics have become increasingly intertwined activities in the knowledge-intensive society. Young (2008) refers to a technical–instrumental orientation to the curriculum where knowledge itself is not valued. Instead, it is the knowledge as an instrument for other external goals that has been a non-questionable point of departure in education policymaking.

The Swedish case of curriculum change illustrates the influence of transnational education policy movements, the significance of previous Swedish curriculum reforms, and the reforms' impact on teachers in terms of their way of organizing teaching and assessing students' knowledge development. Closer analyses show a fundamental shift in the curriculum design that can be attributed to a transnational influence in terms of standard-based curricula characterized by a clear link across goals, content, and results. It represents a kind of denationalized and instrumental educational thinking created by two international influences—a technical–instrumental curriculum discourse focusing on results, and a scientifically rational curriculum discourse on given subject knowledge. Not least, the standardized knowledge requirements focus on clear (summative) assessments of the degree of achievement, which also affects the choices of teaching content and of teaching methods, as teachers' work with assessment and grading. Teachers' professional agency and curriculum work have become more focused on the application of the curriculum (the curriculum as a matter of facts for transmission) rather than on further developing content and forms together with students (the curriculum as a common matter of concern (Wahlström, 2022)).

Conclusions

The questions on knowledge and the curriculum are enduring concerns. In this chapter, key concepts, distinctions, and developments that frame the international discourse have been addressed. Three fundamental dimensions of the curriculum have been illustrated—the institutional, the programmatic, and the textual curriculum concerning the question of knowledge. Given the present situation with international comparisons and standardization in curriculum policy, these provide critical observanda. There is much debate today between subject-matter specialists in curriculum and instruction and curriculum generalists. While subject specialists hold that knowledge is structured differently in each discipline or field, generalists think that foundational considerations must address knowledge from myriad realms of human endeavor and not epistemology alone. Thus, it may be correct to conclude that the structures of knowledge conversation remain unsettled, enabling educators to keep alive basic questions of what is worth knowing in fast-changing knowledge economies.

The knowledge questions about the curriculum designs (i.e., as policy programs) are highly topical in most countries. A strong transnational policy trend in the curriculum area that contributes to this is the so-called key competencies of the future or the capabilities of the 21st century. They emphasize competence, skills, and learning outcomes in favor of knowledge content (see, e.g., Nordin and Sundberg, 2016). Powerful political actors, such as the OECD and the European Commission (EC), have come to advocate a competency-based curriculum and soft governance, together with increasing policy coordination, which have a significant influence on national curriculum discourses and curriculum models.

Whether the selection, organization, and assessment of knowledge or the institutionalized subject structure will change remains an open question. The dominant and traditional premises for organizing the schools' knowledge content are based on an additive logic. When different societal changes call for changes or when new subject areas are added within the various subjects' knowledge development (i.e., within research and the subject disciplines), new content is usually added to the existing subject structure. A historical review clearly shows significant stability regarding the subject structure in Swedish curricula (Sundberg, 2021). Since 1842 (when compulsory schooling was introduced), subjects such as mathematics, the mother tongue, history, geography, religion, music, biology, and drawing have made up the cognitive architecture. Since the 1960s, social studies, foreign languages (English, German, and French), gymnastics, physics, chemistry, and technology have made their way into the Swedish curricula. The only new subject since 1980 is the mother tongue for immigrants. This clearly indicates that a scientifically rational conception of knowledge

(essentialism) is strongly institutionalized within the educational system and constitutes a guiding premise in curriculum work (Sundberg, 2021).

However, in many countries worldwide, curriculum reforms are where subject renewal and integrative principles of content organization are tested. Given the rapid development of knowledge and new societal challenges, it has been argued that new selection principles and opportunities to integrate new content with subjects in new subject constellations will likely become increasingly important to avoid ending up in an overloaded curriculum preparing for tests and where new content is constantly added without existing content disappearing. Sustainable development is an example of such an area that is given an interdisciplinary character and more projected space in the curriculum. In this shift, a learning-oriented curriculum ideology has, above all, been a driving force. Social reconstructionism as a curriculum ideology addresses the future challenges and values at stake in setting the direction for future education.

Glossary

Circumdisciplinarity (from Latin *circum*, “around”, accusative adverbial of *circus*, “circle”) takes into account not only academic and disciplinary knowledge but also others knowledges (experiential knowledge, common-sense knowledge, knowledge of otherness, etc.) that practitioners (specialists, teachers, learners, etc.) incorporate into their practices (see Lenoir, 2000; Lenoir et al., 2006)

French Republican tradition « the French Republican tradition [...] posits state guaranteed non-domination as a definition of liberty, and is built on the foundation of individuals’ ability to go beyond individual interests and adherences in order to work together in constructing an egalitarian political society » (Lenoir et al., 2015, p. 44)

Integration refers to three complementary meanings related to interdisciplinarity. First, it refers to the interrelated learning processes implemented by students (integrating processes); second, it refers to cognitive outcomes achieved by students (integrated knowledge), and third, to an interdisciplinary approach implemented by the curriculum or by the teacher (integrative approach)

Intradisciplinarity refers to the interrelations established in an area of a disciplines based on its internal logic. For instance, interdisciplinary links can be made between geometry, arithmetic and algebra, as these are all components of mathematics. In education, it is also possible, for example, to conceive the establishment of links between history, geography and economy as humanities

Interdisciplinarity in its broader (and common) sense, is often used as a generic term to designate any type of link that can be made between disciplines. Using the term polydisciplinarity would surely be more useful. Strictly speaking, interdisciplinarity refers to real interactions between two or more disciplines concerning their concepts, methodological procedures, techniques, etc. It is therefore incompatible with any kind of cumulative perspective, as it imposes authentic interactions

Mediation two-tier regulatory system: (1) as a process by which a learning subject establishes a cognitive relationship to the object of knowledge (intrinsic mediation); (2) as a process of didactical-pedagogical intervention of the teacher on cognitive mediation carried out by the pupil (extrinsic mediation)

Monodisciplinarity (or unidisciplinarity) refers to the involvement of one single discipline

Multidisciplinarity simply refers to the involvement of two or more disciplines, without specifying the presence or absence of links between them, or the types of links established

Pluridisciplinarity refers to the basic juxtaposition of two or more disciplines where disciplinary specialists work side by side in an additive manner, and without integrating effect. It also implies the absence of any kind of direct link between these disciplines, with no integrative effect. In the academic context, pluridisciplinarity is often characterized by a thematic approach in which a question is addressed separately by different academic disciplines, the only common thread being in fact the theme in question. It refers to pseudo-interdisciplinarity

Transdisciplinarity like many other concepts, is loaded with many senses: (1) it can be understood, first of all, in the sense of cross-disciplinarity (transversality) between two or more disciplines (across) (for example, Barbier, 1997); (2) in the sense of exceeding a discipline, leading to scientific unity based on a group of unifying principles, concepts, methods and goals acting on a metascientific level (beyond) (for example, Nicolescu, 1996); (3) as understood for example by D’Hainaut (1986), in the sense of focusing on behaviors (below), or, as Hamel and Orival (2017), in the sense of a philosophical knowledge to guide practical intervention; (4) it is also used instead of the term “interdisciplinarity”, thereby undermining its own relevance; (5) in the sense of cross-disciplinary mobilization in the context of a project, as understood by Fourez et al. (2002). Morin (1990), who also repudiates previous conceptions of transdisciplinarity, suggests that it should be considered as an approach that allows « to distinguish, separate, oppose, therefore disjoin relatively these scientific fields, but which can make them communicate without operating the reduction » (p. 127), to be able to « account for the multidimensional characteristics of

any reality studied (Morin, 1990, p. 309); (6) in the sense of circumdisciplinarity, taking into account at the same time disciplinary knowledge and also others knowledges (for example, Klein et al., 2001; Lawrence, 2019)

Introduction

Over the past few decades, some of the teaching curricula in the Western world from primary school up through university have advocated the use of interdisciplinary approaches to education. This is shown, for example, by the CROSSCUT project (Cross-Curricular Teaching) funded by the European Commission since 2016 (Reverdy, 2019), by the book edited by Darbellay et al. (2019) which includes the implementation of school interdisciplinarity in different European countries, or by the 2010 special issue of the journal *Issues in Integrative Studies* (Lenoir and Klein, 2010) as regards primary and secondary education (designated as “basic education” in this article) across nine Anglophone, Francophone and Hispanic societies. It is now clear that teaching curricula have undergone substantial change over the past decades. For example, some have grouped together school subjects into subject domains, as in Quebec programs. Even more importantly, they have opened up to questions directly connected to social preoccupations, i.e., to peace, health, civic, environmental, and other types of education; this is what is illustrated by the “educations to” in Quebec, the “convergence themes” in France, the “transversal themes” in the programs of the French-speaking community of Belgium or the “transversal capacities” in French-speaking Switzerland. In addition, today’s curricula stress a strong contextualization of teaching–learning situations, to root them in experienced realities. These pragmatic and/or cultural necessities (social practices of reference) consequently call also for transdisciplinarity that cannot be treated here.

In this article, we will examine interdisciplinarity only in connection with these primary and secondary levels of instruction. The interested reader can consult the glossary or Klein (1990, 1996, 2002) and Lenoir and Hasni (2010) for the taxonomy of interdisciplinarity to which we will be referring in this text as needed. We wish, firstly, to highlight at once the existence of three different fundamental conceptions of interdisciplinarity in education, which, in our view, should be strongly complementary and, then, to present results of many studies we have conducted for 40 years on teaching practices in Quebec to expose that the concept of interdisciplinarity has multiple significations (four overall) that create semantic confusion, to say the least, and ultimately practices that are not so interdisciplinary. Secondly, we suggest arguments which can justify this approach. In other words, which aims can be pursued to apply school interdisciplinarity, as opposed to monodisciplinarity? Or why implement interdisciplinarity in basic education? Thirdly, we suggest six foundational principles by which to found, describe and advise the implementation of interdisciplinarity in education. We will conclude by a definition of school interdisciplinarity.

Some interdisciplinary conceptions in education

Interdisciplinarity has been a preoccupation of school systems since the end of the 19th century in the United States and has been the subject of numerous debates since then (Boix-Mansilla and Lenoir, 2010; Klein, 1990; Kliebard, 1992a). Only in the 1960s and 1970s, however, with the development of economic and cultural globalization, the internationalization of exchanges, and various social and economic pressures, did it significantly emerge in the European world (Ansart, 1990; Apostel et al., 1972), and later still in the Spanish-speaking world (Fazenda, 1994, 1995; Miñana Blasco, 2001). This has been documented in particular by the articles published in the special issue edited by Lenoir and Klein (2010), which respectively provide a historical portrait of the emergence of interdisciplinarity in basic education in North America (United States, Ontario and Quebec), South America (Colombia), Europe (Spain, France and Switzerland), and Australia. While these articles may show that the conditions and circumstances under which interdisciplinarity emerged are different in each country, they also show that « the emergence of the concept can essentially be traced to two sources: government decisions and economic pressures in line with the requirements of a global market economy » (p. xi). They also suggest the existence of « a close link today between the competency-based approach and the recourse to the interdisciplinary perspective in curricula » (p. xi), a link which, moreover, is based on various epistemological foundations and/or neoliberal and/or utilitarian perspectives.

Three different logics

It is worth noting here that each society has approached the issue of interdisciplinarity in its school system in its own way, depending on its unique historical, political, cultural, social, educational, and other features. An anecdote eloquently attests to these different interpretations of educational realities. In 2002 a reform of initial teacher education was announced during a departmental assembly at the university where we work, in a context where the previous reform had not yet been completed and the new one was to be applied the following year. Several of our colleagues have the reaction: « What are we going to do? » This reaction left me a strong impression. During a trip to France the following month, we presented this issue to colleagues at the universities of Nantes and Toulouse. Their reaction was completely different. They asked, « Why the reform? », « How does it change the training content? » Two months later, we found ourselves at the Catholic Pontifical University of São Paulo where we have been invited by our colleague

Ivani Fazenda. Her reaction and the reaction of her students to whom we have presented the same issue were very different: « Would I feel good in this reform? » These were three very different reactions to the same situation, already indicating the existence of distinct interpretations.

By more extensively examining the Anglophone North American and Francophone European perspectives (and, later, a certain Latin American and Brazilian perspective), we have been able to identify a series of factors that might explain the existence of distinct socio-historical logics and their underlying rationales. These logics can be illustrated based on a second real-life anecdote. In 2000, at an international conference, we invited 32 researchers from various European countries (Belgium, France, Switzerland), North America (Canada, United States), and South America (Argentina, Brazil, Chile). The European participants extensively discussed the relevance of implementing interdisciplinarity, the meaning it should be given, and its impact on the hierarchy of scientific disciplines (the tree of science). Gordon Vars and Julie Klein from United States then took the floor and wrote on a board to explain, in a few very systematic points, how interdisciplinarity can be operationalized. As for the Brazilians, they put on music and projected slides

Although we must avoid over-generalization and caricature, these two concrete examples taken from direct experience, and supported by critical analysis of many publications originating from these three cultures, show just how differently the notion of interdisciplinarity can be interpreted. We have been able to highlight the existence of three distinct logics (Fig. 1) that result from sociohistorical and cultural factors (Lenoir, 1999, 2002, 2005; Lenoir and Hasni, 2004; Lenoir et al., 2015, 2001).

In Francophone Europe, and especially in France, interdisciplinarity is strongly marked by rational Cartesian thought and the influence of philosophers (including Voltaire) and the Encyclopedists in the Enlightenment period (Sachot, 2001, 2004). Hence, in this country, the search for meaning, rational logic, and consequently the epistemological perspective (Resweber, 1981) and the relationship to knowledge (Beillerot, 1989; Charlot, 1997) are central and omnipresent to interdisciplinary reflection. In the school context, the debate most often centers on protecting disciplines' specific identities, rather than forging interdisciplinary links (Durkheim, 1969/1938; Stichweh, 1991). Socialization in the school context, for its part, is above all conceived as the transmission

Fig. 1 Three distinct readings of interdisciplinarity.

of cultural heritage in direct connection with a universalist vision consistent with the French Republican model. Subject-specific didactics is therefore omnipresent since it intends to analyze the knowledge to be taught in order to make it accessible to students (for example: Fourez, 1994, 1998; Fourez et al., 2002; Lenoir et al., 2015; Reuter, 2019; Lenoir, 2000).

The North American English-speaking logic is based on other references. The break at the end of the 19th century with the educational model inherited from the United Kingdom led to the promotion of pragmatism (Tanner and Tanner, 1990; Rudolph, 1977). This change has highlighted the importance of know-how (how to do), a functional approach. In the United States, which is dominated by an instrumental (pragmatic and organizational) educational perspective (Klein and Newell, 1996; Kliebard, 1992a,b; Lenoir, 2002; Newell, 2001; Pinar, 1998), school interdisciplinarity is thought of as a search for operational answers to questions that arise within society. This focus on solving societal problems can be characterized as a “project” interdisciplinarity (Klein, 1990; Klein and Newell, 1996; Lenoir et al., 2015) in which the knowledge involved is immediately useful and operational. In schools, the importance of know-how is clearly illustrated by publications that give operational methods for applying interdisciplinarity in class (e.g., Clarke and Agne, 1997; Fogarty, 1991, 1993; Frazee and Rudnitski, 1995; Jacobs, 1989; Pollard and Tann, 2002; Tann, 1988; Vars, 1993). As noted in Lenoir et al. (2015), « In the United States, the focus on the functionality of learning can be traced back to the pragmatism established at the end of the 19th century. This pragmatism should be associated with the preoccupation, dating to the same period, with placing the individual student at the heart of learning (the “subject pole”). Indeed, the need to socially integrate masses of immigrants necessitated a focus on pedagogical practices (to facilitate learning processes) and socialization processes (to foster civic skills). These two fundamental traits of the North American curricular conception have underpinned the professionalizing orientation of its education system. In the United States, the priority appears to be the adherence to the “virtues” and values of American society (personal skills) as well as know-how geared toward problem solving » (p. 66). Hence, the French epistemological search for meaning stands in contrast to American functionality, even if this does not preclude the existence of other interdisciplinary currents in the school context.

In addition to these two distinct approaches to interdisciplinarity—one primarily involving knowledge and the other know-how and certain personal skills—it is important to acknowledge a third, which is strongly expressed in a certain Brazilian conception of interdisciplinarity. The perspective adopted in this case is clearly phenomenological and involves a symbolic interactionism. The emphasis is on the actor as a medium for interdisciplinarity, and therefore on the subjectivity of individuals who are integrated into everyday life and on their methodological intersubjectivity. The main concern is the process of continually constructing the individual in a situation, a process involving not only self-knowledge, but also knowledge of others (Fazenda, 1994, 1998). In the Brazilian logic, which is profoundly subjective (and intersubjective), school interdisciplinarity is mainly focused neither on a reflexive function with regard to knowledge, nor on a pragmatic function. The predominant aim is rather to pursue the realization of the human subject by stressing the integrating “I”, not the relationships between disciplines, and even less functional and pragmatic action. From this affective perspective, interdisciplinarity above all has to do with the internal interactions of the subject, as he or she searches for answers to personal questions. The idea might be described as an introspective interdisciplinarity that is founded on a phenomenological search for the self. We will come back to these three perspectives at the end of the following section in order to underscore the need for complementary relationships between these perspectives in school interdisciplinarity.

Finally, in order to make the problem of interdisciplinarity even more complex, it would be essential to specify the type of interdisciplinarity we are talking about and which we intend to use. In fact, interdisciplinarity is part of the field of practical, scientific, vocational and academic operationalization. Each of these perspectives has specific purposes, reference systems, study objects, and operational modalities (Lenoir, 2019). Here, let us say again, we are only talking about school interdisciplinarity.

Interdisciplinary conceptions and practices in Quebec education

It is not enough to use the word “interdisciplinarity” for a given practice to accurately correspond to the concept. The many studies we have conducted for almost 40 years on teaching practices in Quebec have allowed me to identify Quebec teachers’ representations of interdisciplinarity at school as well as its implementation in their teaching practices (Lenoir and Hasni, 2010). The results of these researches in schools have brought to light that interdisciplinarity exhibits a polysemy sometimes bordering on cacophony (Fourez et al., 2002). This polysemy is of little help in circumscribing the term’s meaning(s) in terms of its scientific basis. The word is clearly fraught with incoherence that has led to errors and obscurities. The concept of interdisciplinarity is given multiple significations that create semantic confusion, to say the least, and ultimately practices that are not so interdisciplinary. Analysis over the past 30 years has identified four groups of conceptions and teaching practices in the school context—pseudo-interdisciplinary, hegemonic, eclectic and holistic—which show different degrees of proximity to the scientific foundations of school interdisciplinarity (Fig. 2).

Placed on a cartesian axis (x and y), these four dominant approaches make up the extreme poles of two intersecting continua. The x axis (holism-eclecticism) concerns the degree of fusion or dispersion of school disciplines, while the y axis (hegemony-pseudo-interdisciplinarity) concerns the intensity of relations between disciplines, ranging from domination to the absence of real links. The two-sided arrows ac and bd illustrate the fact that interdisciplinary practices can be associated with one approach or lie somewhere between two approaches. The circle at the center of the diagram represents the interdisciplinary perspective we will present further on.

The results of various researches show that a theme-based pseudo-interdisciplinary is especially often preferred by first-cycle primary teachers. This tendency is mainly caused by their significant preoccupation with awakening student interest, in which case the relational and psycho-affective dimensions (together with the organizational dimension) take up a preponderant place

Fig. 2 The poles of interdisciplinary practice.

in their interventions with students, to the detriment of cognitive dimensions. On the other side of the spectrum, the hegemonic approach, in which certain disciplines are in fact no more than a pretext for teaching other disciplines, may be explained by the priority certain teachers give to teaching the language of instruction. The eclectic approach, which is profoundly destructuring, since, to quote [Jacobs \(1989\)](#), it perceives learning content as a “pot-pourri” from which one can pick at random, is also commonly observed in teaching practices. The holistic approach, which is based on the negation of all disciplinary specificities in the name of a natural approach, is frequently observed among teachers adhering to pedagogical conceptions that promote an open and active pedagogy centered on student interest, thereby sidelining cognitive objectives. These four approaches are in some cases used by teachers whose primary aim is to meet curricular requirements from a strictly administrative point of view. When this happens, these approaches serve mostly as justifications for the absence or near-absence of the teaching of certain school disciplines that are officially mandatory and planned for in the program, but in fact considered secondary from a societal point of view. This situation especially applies to the teaching of the arts, natural sciences, and humanities. These different trends have been presented in [Lenoir and Klein \(2010\)](#). For example, pseudo-interdisciplinarity, if not eclecticism, can be found in Australia ([Long et al., 2010](#)) and eclecticism, along with the hegemonic perspective and holism, can be found in Colombia ([Rodriguez and Miñana Blasco, 2010](#)). Likewise, the hegemonic perspective can be noted in teaching practices in Ontario ([Clausen and Drake, 2010](#)). It has also been identified in an article by Baillat and Niclot on France ([2010](#)) and an article by [Segovia et al. \(2010\)](#).

The discourse on interdisciplinarity therefore conceals practices most often marked by the primacy of certain socially valued disciplines and a dilution of the socialized knowledge of “secondary” disciplines. It can be hypothesized that teachers’ use of “interdisciplinary” practices is based on two key preoccupations: first, gaining time, and second, boosting student interest and motivation via thematic approaches or projects. The cognitive contributions ultimately receive little consideration. This state of affairs connects with the “practical logic” of [Bourdieu \(1980\)](#). Practices are “practical” in that they are « capable of producing intrinsically coherent practices » (p. 145) in a given situation, and in that they involve the principle of an economy of logic. In other words, they are simple and useful because they are based solely on a few generative principles that are strongly interrelated and impose the structuring of (and structuring within) action. In short, this logic—which we associate with the world of common sense—can be easily mastered, managed, and put into practice, thus requiring little time and energy.

Among many other results, we have highlighted the strong hierarchy of school disciplines. The reasons are not primarily school-related, but social, political, and ideological-economic. The importance of the disciplines does not, however, depend *a priori* on

government discourse, which is also influenced by pressure from lobbies and social groups. Their importance depends on the value that society and institutions actually assign to them. In this vein, British sociology research (especially by Bernstein (1971a,b) and Young (1971), who contrast a compartmentalized curriculum with an integrated one) underscores the intrinsic hierarchical character of a compartmentalized curriculum and the very powerful process of social selection and control that it implies.

In contrast to these different and more or less skewed interpretations, we consider that school interdisciplinarity postulates the establishment of mutual dependence, free of predominance or neglect, between school subjects. We will come back to this point. Such an epistemological, social, and political posture leads to a different reading of curricular components, one based on a search for the specific identity of each discipline (its place and function on the cognitive and social levels) as well as the complementarity of contents that is needed in order to apprehend, communicate, and relate to natural, human, and social reality. This posture also calls for a critical position toward the hierarchy of school disciplines and the resulting function of social selection. To return to the perspective developed by Bernstein, the “serial” (additive or cumulative) conception of curriculum implies opacity, rigidity, and hierarchy, while the “integrated” (we might say “integrative”) conception promoted by interdisciplinarity involves permanent inter-activeness, a sharing of power between teachers and between teachers and students, and a necessary transparency about the aims and goals that are being pursued.

Some arguments to implement interdisciplinarity in school education

As most interdisciplinary authors point out, current social and economic transformations would be at the origin of curricular changes with an interdisciplinary, if not transdisciplinary, tendency. Traditional disciplinary and often compartmentalized models would no longer meet the needs of students and societies, of complex social and environmental issues that require comprehensive, integrated analysis and understanding. It is important to recognize the complexity of the natural, human, and social reality in which we live, as well as the fragmentation of the knowledge transmitted in schools. This perspective has been elaborately presented and described by Apostel et al. (1972), Klein (2002) and Torres Santomé (1998), among others.

Thus, interdisciplinarity would become an element of response to the complexity of the actual world. This perspective, which fights against fragmentation, was presented at length and explained among other things by Morin (1977, 1990). While simplification has led to great scientific discoveries in the natural sciences, « nature is a polysystemic whole » recalls Morin (1977, p. 100), the study of human beings, their relationships and social practices absolutely require the use to the complexity where the interrelationships between the constituent elements are grasped as organized systems. So, we are simply pointing out this central argument, which is certainly a very important one, to justify the use of interdisciplinarity. But in the context of youth education, we would like to point out other arguments that directly bear on teaching–learning processes. These arguments are based on the fact that school learning takes place in a specific context, namely the physically closed space of the classroom, that is, a system of interactions among pupils and between them and the teacher. So, we would thus consciously like to examine aspects that are less often considered when dealing with school interdisciplinarity in general.

It is important to recall, first of all, that students 6 to 16–17 years old do not generally study out of a love for the school disciplines, but instead, one might say, out of a “love” for the teacher. More specifically, although we could not develop here the entire set of arguments that originally stemmed from dialectic Hegelian thinking (Hegel, 1941/1807, 1969/1805) and that has been developed by so many researchers, including Kojève (1947), Lacan (1966), Lordon (2010, 2011/2006, 2013) and Honneth (2013)—and well before them by Spinoza (1849/1667), who described it as the essence of human nature and the driver of action (the *conatus*)—the student strives to capture the desire to know that he/she decodes in the eyes, attitudes, and discourse of the teacher. The student’s behavior in class is then dictated not by the need to know, but originally by social, intellectual, and affective relationships that he/she develops with the teacher with the intent of appropriating the qualities decoded in the teacher and obtaining recognition of value as a human being (Lenoir, 2017/2014). A love of knowledge may develop only subsequently. The teacher’s role is therefore crucial. An interdisciplinary approach in this context assumes an important function of facilitation; however, it will only do so insofar as it takes into account the following.

First, interdisciplinarity requires teaching–learning situations that stimulate research practice—for example, “a-didactic situations” (Brousseau, 1998) and “problem situations” from a constructivist perspective—and that can make sense for students on the epistemological (the relationship to knowledge), ontological (the relationship to the subject) and social (the relationship to life in society) levels. The situation must be contextualized, and such a contextualization must necessarily be multi-dimensional, given that, to be understood the situation requires an interdisciplinary approach.

Yet for many students, distinguishing between everyday life and school life is problematic. Scholars such as Bernard Rey of the Université Libre de Bruxelles (private communication) have observed misunderstandings that arise when students are confronted with a proposed situation. Let us take a real-life example: when Professor Rey, who had been invited to a classroom, asked students how to take the train to go home, the route to take, the distance, the duration of the journey (which required the use of mathematical and geographical knowledge), a student immediately answered him that he shouldn’t worry, that his father was not working that day and would be pleased to drive him to the station on time. Joël Bisault (2011), of the École normale supérieure de Cachan in Paris, has likewise underlined problems of interpretation in school assignments among primary students by showing that some adopt a “domestic point of view.” This misunderstanding has also been noted in other studies of classroom practices in Quebec. For example, a study of four teachers’ instruction on plant parts (biology) shows that hypothetical situations that are strongly anchored in everyday life (an aunt’s organization of a food shopping basket into fruits and vegetables) can be an obstacle to posing

scientific problems. In this case, the students' interpretations of the situation led them to focus their verbal exchanges on their everyday knowledge of fruits (such as their sweetness and juiciness) or on men and women's culinary skills (use of fruits and vegetables) (Hasni, 2011).

There is a real trap that students can become engaged in exclusively relational, affective, domestic, and other readings of the situation if the contextualization remains superficial and incomplete. This problem persists in secondary school. Suffice it to say that if contextualization is not adequately developed, there is a risk that students will differently interpret the instructions and tasks given by their teachers, because they will not decode the school task within the situation. The issue is with the student's task, as opposed to the child's or adolescent's task, that is expected of them, because they may perceive only the visible (external) facet of the task to complete. They might also be unable to assign meaning to the situation or the task itself (the internal context) and lose interest and motivation in the work that is expected; in short, they "disconnect." Indeed, this is one of the factors leading to a lack of interest in school and cases of dropout. In short, the interdisciplinary perspective in school fosters students' search for meaning, in terms of the knowledge (epistemological perspective), the subject (ontological perspective), and the engagement in life activities (social perspective) that are involved.

Second, because of the need to use varied disciplinary knowledge, interdisciplinarity calls for the use of what Boix-Mansilla (2017) refers to as a pragmatic constructionist epistemology and to what Martinand (1986) called "basic social practices" and Vygotsky (1987, 2014) "everyday concepts". Pastré (2011) works on vocational education in France highlighted the conceptual structure of a situation and the centrality of effective knowledge in practice, as well as the importance of these social practices and more particularly of practical concepts needed to organize the action. That is why we suggest the use of the concept of circumdisciplinarity or transdisciplinarity if the latter is properly designed.

The fundamental *raison d'être* of such a pluralist epistemological concept is to promote and support students' construction of meaning. Precisely because students struggle to distinguish between everyday life and school life, between common sense learning and school-related learning, we believe it is necessary to use the springboard of teaching-learning processes that involve situations anchored in reality. This allows teachers to leverage students' life experiences, as well as the pragmatic notions and concepts that they use in their everyday lives and that are indispensable for organizing action. Vygotsky (2014) had already established a link between everyday concepts and scientific conceptualization processes. Real-life situations allow students to invest themselves based on their life experiences, so that they can inter-subjectively debate their different conceptions, and then, with the teacher's help, progress toward the use of scientific approaches and toward the production of abstract and general concepts.

We postulate here, without being able to develop it, that knowledge is not in the head of individuals and that it is not their property, but that it is a dialogical, intersubjective process that establishes itself in class. Here we join the conceptions of social constructionism of Gergen (1994, 1995). However, if, in everyday life, pupils communicate, build knowledge, solve problems, experiment, these different processes are part of the common sense. But school must be the place where they move from these processes acquired in everyday life to scientific approaches that involve the critical and thoughtful objectification of actions systematically and explicitly laid: communicating, conceptualizing, problem solving, experimenting, etc. To take only this last approach, it is necessary to distinguish between expressing an opinion and carrying out an experiment. That is why test and error and empirical groping are starting points to be overcome from an integrative perspective (Lenoir, 2017/2014).

Even if, in everyday life, students communicate, construct knowledge, solve problems, and carry out experiments, these different processes tend to come down to common sense. School should be a place where they make the transition from these processes acquired in everyday life to scientific approaches that involve a critical and well-considered objectivization of actions that are carried out systematically and explicitly: communicating, conceptualizing, problem-solving, realizing, experimenting, etc. To address only this last process, a distinction must be made between giving an opinion and conducting an experiment. This is why trial and error, and empirical efforts at understanding, are a point of departure that must be moved beyond from an integrative perspective. Student action is therefore a point of departure, but also a stumbling block. Education must indeed focus on the need to apprehend a subject who is "capable", who can say "I can" or "I cannot," and not only epistemological subjects who "know," who master knowledge and who can say "I know" or "I do not know." Interdisciplinarity carries with this conception of an inseparable bond between cognition and functional action, for "I can" if "I know". In short, the interdisciplinary perspective precisely requires the interrelated use of a number of scientific processes.

Allow us to give a real-life example that illustrates the need to anchor teaching-learning processes in the realities of students. Invited to a classroom by a teacher in order to do a science activity, we asked the students, based on the program objectives at the time, to design, draw, describe, and explain the production and functioning of an object that could make noise as it moved (thereby using science, technology, drawing, and French). The students worked in teams and one of them helped out most of these teams. However, before entering the classroom, the teacher had told us that the student who was helping all the others was the most difficult, the least cooperative; that was why he was seated at the back of the class. When we congratulated the student, who was one of the most pleasant and helpful during the entire activity, for his valuable help and the quality of guidance he gave to other students, we also asked how he had developed these skills. The student answered that his father was an engineer and that he liked to imitate him. This may have been a happy coincidence, yet interdisciplinarity clearly offers the possibility of giving meaning to learning activities.

A third contribution of interdisciplinarity in basic education has to do with the need for complementarity and overlap in the scientific processes to which we have just referred. Rather than naively or unconsciously—or neglectfully—employing only problem solving, interdisciplinarity can (among other things via a problem- or project-based approach) support the development of integrating learning processes. It is able to do so through the use of several approaches required by the necessary complementarity

of diverse disciplinary outlooks, namely conceptualization, problem-solving, communicational, experimental, esthetic and other processes. It also stresses the fact that problematization is central to a teaching/learning process, and that scientific approaches are cognitive processes that must in themselves be an object of learning. It is impossible, for instance, to produce an experimental protocol without having first conceptualized the experiment's components; and the results, for their part, require a communicational approach. As a result, interdisciplinarity in the school, in its training function, must promote the use of an integration of scientific processes.

Fourth, and this point connects with the question of metacognition and the self-regulation of learning, interdisciplinarity is only genuinely meaningful if metacognitive processes are introduced and promoted by the teacher, and if they are applied by students. What has been observed in everyday life is that teachers teach knowledge, sometimes by making links between different school disciplines, but they forget or neglect the metacognitive processes that are indispensable to ensure effective learning. While they are often led to ask students whether they enjoy an activity, and hence call upon affective dimensions, they forget the cognitive and procedural dimensions. Indeed, only rarely does one hear a teacher asking the students, « What have we just learned? », « How did we arrive at this knowledge? », « What pathway, what steps have we taken? », « What difficulties did we come up against? », « How did we resolve these difficulties? », etc. Students' initial representations need to be collected and held on to so that they can be referred to and compared during a culminating synthesis' activity, in order to take stock of the cognitive ground that has been covered.

The following example clearly illustrates this absence of a metacognitive process. In a class during last year of primary school, a teacher gave students an aerial photograph of their village. Several students immediately said that the picture was of Quebec. We will not describe all the activities held by the teacher, including a field trip to the village with direct observation, graphic representations, the production of texts, etc. Following these activities, the same students said, « We knew it all along, it's our village! », thereby forgetting their initial representations, which had not been collected. Moreover, the teacher had not given the students an opportunity to apply the metacognitive processes that would have allowed them to integrate both the procedural processes by which they had constructed the new knowledge and the knowledge itself. As a result, there was no guarantee that this knowledge and especially the approaches implemented have been acquired and that the capacity to reinvest it in the future had been developed.

Finally, fifth, and not least, interdisciplinarity needs the establishment of a reciprocal dependence, without any predominance or ignorance, between school disciplines. Such a posture, at the same time epistemological, social and political, leads to another reading of the components of a curriculum based at the same time on the search for the specificity of each discipline (its place and its function on the cognitive and social planes) and the necessary complementarity of its contents to apprehend and communicate the natural, human and social reality, and to enter into a relationship with it. It also elicits a critical position on the hierarchy of school disciplines and the resulting social selection function (Bernstein, 1971b; Gosselin et al., 2005; Lenoir et al., 2000; Pate et al., 1997; Wineburg and Grossman, 2000).

In the few points we have just presented to justify the use of interdisciplinarity in basic education and to discuss a few of its aims, the reader will note that we have called upon the mind, the hand, and the heart, that is to say, the cognitive, pragmatic, and ontological dimensions.

Fundamental principles to guide the implementation of the interdisciplinary approach in education

While several characteristics to be respected are already in the previous section, we would like to stress here six principles which we believe are fundamental to ensuring a proper use of interdisciplinarity in school education.

The first principle is that there can be no interdisciplinarity without disciplinarity, that is, without formalized cognitive contents, and without their related instrumental and procedural methods, which we refer to in the educational jargon as "learning processes," i.e., methodological processes that make it possible to construct the knowledge prescribed by the curriculum, to experiment it, to resolve it, to communicate it. Although this might be construed as stating the obvious, we would like to recall, following Klein (1996), Newell (1990, 1998), Petrie (1992) and Wineburg and Grossman (2000), among others, that reflection on interdisciplinarity is only meaningful in a disciplinary context and that it presupposes at least two reference disciplines as well as the presence of reciprocal action. The term "interdisciplinarity" itself makes this relationship as a requirement: "inter-disciplinarity" subsumes "disciplinarity"! Numerous definitions of interdisciplinarity that have been researched attest to this position by admitting, at the very least, some kind of relationship between various core components of at least two disciplines, i.e., subjects, contents, processes, techniques, etc. We could talk about the "disciplinary complexity principle". In other words, interdisciplinarity must be designed to facilitate cognitive learning that is at the heart of school function (Lenoir et al., 2016).

The second principle is that interdisciplinarity conceives all school disciplines as important and complementary in constructing and understanding reality. As Haynes (2002) points out, « No disciplinary viewpoint is inherently or universally true or superior to others » (p. xv). School interdisciplinarity must be understood from a relational standpoint, since, to achieve learning, it strives to establish exchanges, connections, and complementary links between school disciplines. This is why it is important to move beyond the views, at first glance antithetical, between theoretical, methodological, instrumental, and critical interdisciplinaries (Gosselin et al., 2005; Klein and Newell, 1996) in the school context. Indeed, each discipline in the curriculum exhibits these features. The disciplines should be used in complementary fashion, particularly to avoid extreme practices such as Platonic pure ideas or a mere technicist application. Hermerén (1985) further notes the complementarity that is needed, from a knowledge integration perspective, between knowing "that," associated with school interdisciplinarity, and knowing "how," associated with instrumental

interdisciplinarity, i.e., between the knowledge he describes as propositional (declarative knowledge) and operational knowledge (procedural knowledge). The “principles of equality, necessity and complementarity” between different disciplinary contents is indispensable; moreover, it stands in contrast to a distinction between primary disciplines, seen as more important, and secondary disciplines, seen as inferior. Instead, it suggests the importance of taking into account the specific identity and functions of each mobilized discipline and its contributions.

This is why interdisciplinarity must be clearly distinguished from multidisciplinary and, above all, from pluridisciplinarity. It is not based on a cumulative perspective, just as a house is more than just a pile of stones, to paraphrase a metaphor from Poincaré (1917). Indeed, interdisciplinarity is incompatible with the tendency to believe that mere physical proximity between people—in this case teachers of different subjects—would be enough to make an educational activity interdisciplinary. Nor is interdisciplinarity compatible with an “additive” vision of disciplines and content. Moreover, it is insufficient to acknowledge the multidimensionality of a real-life situation and the possibility of interpreting it in different ways to bring about interdisciplinarity. The fact that students may be taking a course in one or more other disciplines does not make their education interdisciplinary; at first glance, in any case, we are dealing with multidisciplinary, if not eclectic education. Nor does a field trip to a farm, and the subsequent use of this theme to produce activities in French, mathematics, science, arts, etc., make the approach interdisciplinary. In this case we are dealing with pseudo-interdisciplinarity that is in fact pluridisciplinary in nature. Gusdorf (1967) refers to this frequent “magical mentality” toward interdisciplinarity as an erroneous view that consists in « bringing together specialists from different areas believing that such an encounter would be sufficient to establish a common ground and common language between these individuals who, in fact, have nothing in common » (p. 1089). In short, interdisciplinary practice requires a real complementary interaction between the disciplinary contents where all the school disciplines possess an equal importance, due to their required complementarity and their necessary collaboration, according to the intentions pursued in the teaching–learning process. Again, it is here both the “principles of equality, complementarity and necessity”.

The third principle, which clearly illustrates the complexity of the concept of interdisciplinarity, is that there are several epistemological conceptions with regard to the function of interdisciplinarity, which is illustrated in Table 1. The relational perspective, which refers to the “principle of relationality”, is the academic and vocational perspective that characterizes school interdisciplinarity. If the ampliative perspective is especially characteristic of scientific interdisciplinarity, the restructuring approach is essentially linked to the transdisciplinary perspective or to the challenge of science (Lenoir and Sauvé, 1998a,b).

The fourth principle, and perhaps the most important in our view, is that interdisciplinarity in education belongs to the means, rather than the ends. The aim of interdisciplinarity is the integration of learning processes and the integration of the resulting knowledge. The purpose of using interdisciplinarity is to foster the mobilization of knowledge and processes with a view to realizing and successfully carrying out an action. In other words, it is to promote and facilitate students’ integration of integrating processes and integrated knowledge, as well as their mobilization and application of these elements in real-life situations (Beane, 1997; Henry, 1958; Hopkins, 1937). It therefore requires the establishment of integrative approaches by the teacher, and not the imposing of an integrated curriculum where the integrating process itself has already been established from outside, from above, by the designers of the curriculum, textbooks or activities. This is the “principle of integrative finality”. As Klein (1996) rightly points out, « Interdisciplinarity work gets done by moving across the vertical plane of depth and the horizontal plane of breadth. Breadth connotes a comprehensive approach based in multiple variables and perspectives. Depth connotes competence in pertinent disciplinary, professional, and interdisciplinary approaches. Synthesis connotes creation of an interdisciplinary outcome through a series of integrative actions. Synthesis does not derive from simply mastering a body of knowledge, applying a formula, or moving in linear fashion from point A to point B. [...] It requires active triangulation of depth, breadth, and synthesis » (p. 212).

Interdisciplinarity consequently requires the adoption of a socio-constructivist epistemological posture, given that it requires that learning subjects obtain recognition and assert themselves as knowledge producers, and requires that this conceptualization process be part and parcel of the social context. Students’ experience of reality is then no longer a representation of the world “as it is” but rather, as Stengers (1993) aptly states, “a risky invention” (p. 62). This is why it is indispensable for the teacher to introduce the conditions deemed favorable to support and guide students’ implementation of an interdisciplinary approach to the cognitive questions that are addressed. At the same time, however, it must be kept in mind that integration is above all a cognitive process that must be performed by the students and not the teacher or the curriculum.

At the school level, this implies the implementation of an interstructuration model, based on dialog, exchange, where the teacher acts as a mediator on the interaction students establish with the learning contents (Lenoir, 2017/2014). This also requires, among

Table 1 Three epistemological conceptions of the function of interdisciplinarity.

<i>Epistemological options</i>	<i>Characteristics</i>
1. Relational approach (education)	Establish links (complementarities, convergences, connections, etc.), “gateways” (<i>bridge-building</i>)
2. Ampliative approach (research)	Bridging the gap between two existing sciences (research) (emergence of new scientific disciplines) (<i>no man’s land</i>)
3. Restructuring approach (epistemological criticism) that sometimes becomes radical	To question the nature of knowledge itself and to promote the birth of a new concept and organization of scientific knowledge Substitute another structure for the disciplinary structure (for example deconstructionist criticism) (<i>tabula rasa</i>)

other things, a strong interaction between curricular, didactic and pedagogical plans. Indeed, an interdisciplinary approach requires an integrative articulation between the curriculum and classroom practice (Fig. 3).

The transition from the curricular plan to the pedagogical plan or, to put it another way, to the practice of teaching in the classroom, requires the use of the mediation of the didactics of the school disciplines. The pedagogical time of the teacher's updating in class requires to understand the aims pursued by each school discipline, their specificities and the mutual contributions. But it is also important, with this understanding in mind, the design of teaching-learning activities uses didactic dimensions that ensure that learning objects are arranged in a way that makes them accessible to students.

As a fifth principle we call the "principle of integrated logics", and as we have already reported, we must take into account three perspectives to approach teaching and learning: meaning, functionality, and affectivity. These three perspectives are complementary and should be interwoven when using interdisciplinary approaches in teaching practices. Otherwise put, interdisciplinarity requires the mind, the hand, and the heart, meaning a strong interrelationship between the cognitive (or epistemological), practical (or pragmatic), and human (ontological and social) dimensions, which, in our view, are fundamental components of human beings and should be at the core of any educational process.

Finally, the sixth and final principle we would like to suggest is that it is no longer possible today to truly master several disciplines. The era of Giovanni Pico della Mirandola, who in the 15th century set out to conquer all existing knowledge, is long gone. What is needed instead is to pool disciplinary competencies. Consistent with Bernstein (1971a,b), an interdisciplinary approach based on integrated intervention by a teaching team will tend toward an integrating curriculum, characterized by a system of open contents and an "ample education", as opposed to a compartmentalized curriculum based on a hierarchy of disciplines and a rigid and opaque system of closed-off contents. This "principle of collaboration" requires organizational management which is often the real weakness. An interdisciplinary team must not only receive institutional recognition and real support from its superiors, but also a leader who is respected, rigorous and demanding of the team members, who is also able to perform several

Fig. 3 Relations between curricula, didactic and pedagogical plans.

functions: *ringmaster, bridge specialist, gatekeeper, boundary agent, ombudsman, polymath, dynamo, metascientist, specialist/generalist, strong entrepreneur* (Klein, 1990; Klein and Porter, 1990). This leader must also have the necessary competencies to manage team teaching and pedagogical projects, and to regulate actions and interactions (regular fixed, individual and group meetings). Numerous authors (Crawford Burns, 2002; Davis, 1995; Fourez, 1994; 1998; Hasni et al., 2008; Klein and Newell, 1996; Wentworth and Davis, 2002; Wineburg and Grossman, 2000) have shed light on the need for team teaching, which must be undertaken in a spirit of genuine collaboration. In interdisciplinary education, team teaching is required because solving a problem, addressing a question, or carrying out a project all require complementary processes, cognitive contents from different disciplines, etc. Crawford Burns (2002) stresses that « interdisciplinary teams should consider the needs and interests of students as well as the essential content and processes in each discipline and their application to authentic tasks » (p. 68).

Conclusion

In light of the various clarifications we have suggested regarding interdisciplinarity, we would like to propose the following definition: school interdisciplinarity is the action of putting two or more school disciplines into relation on the curricular, cognitive, and operational levels, leading to the establishment of complementarity or cooperative links, interpenetration, or reciprocal action from various standpoints (the aims, objects of study, concepts and notions, learning approaches, technical abilities, etc.). These interactions are aimed at promoting human beings' integration of processes and knowledge (Lenoir and Sauvé, 1998b). In teaching-learning practices, the teacher's role is to establish the conditions judged to be the best, the most appropriate, to promote and support student learning processes. To draw on interdisciplinarity at school is to introduce conditions that are normally favorable to human beings' implementation of integrating processes by mobilizing various and interrelated disciplinary angles. For, indeed, it is not the teacher who must do the integrating, but the students. They are the actors who will do the integrating, insofar as the two following basic conditions are met: first, examining the principal elements of school disciplines and their structure (conceptual knowledge and disciplinary processes) with a view to identifying interdisciplinary perspectives; and, second, implementing teaching-learning situations that require the construction of conceptual knowledge from two or more school disciplines and that require the complementary use of different learning methods.

As a result, rather than tending toward a merging of disciplines, an eclectic addition of knowledge elements, a thematic pseudo-interdisciplinarity, or a hegemony of one school discipline over the others, interdisciplinary practices involve relationships that foster mutual dependence between disciplines, free of any dominance or neglect. They are based on a consideration of the educational aims pursued, acknowledging the wealth of complementary links and of real and essential interrelationships between cognitive contents and methods, which are necessary in order to construct, express and interact with human, social, and natural reality. In a school context, interdisciplinary perspective therefore requires an open relationship between cognitive and practical dimensions, but this relationship must also introduce affective dimension. This brings us back to the idea of the mind, the hand and the heart, insofar as reason (reflected-on knowledge) mediates between the heart (empirical human dimension) and the hand (operational dimension).

Owing to its specific features, the school interdisciplinarity requires that the knowledge stemming from different school subjects be explicitly addressed and treated to enable learning in connection with various learning situations (problems, projects, compelling scientific or current societal question, etc.). In short, it is important to take into account the purposes and the specific identities of school disciplines in any interdisciplinary classroom approach. This is why school interdisciplinarity can under no circumstances be an end in itself: « on an educational level, one can no longer interpret interdisciplinarity without referring to the concept of integration » (Lenoir and Klein, 2010, p. xviii). This is because its aim is to enable students to develop integrative cognitive processes and the cognitive integration of the knowledge that is gained. We thus consider that the notion of integration must include a dynamic and constructive outlook on learning, one that is meaningful and necessitates the use of cognitive elements from different school disciplines, as well as complementary and interrelated inquiry processes across disciplines. Moreover, it requires the realization of a set of principles that ensure it will pursue objectives that are complex, but accessible to students thanks to the mediation of teachers.

It must be kept in mind that the foremost mission of basic (primary and secondary) education is to educate individuals who are capable of living and finding fulfillment in society, while being able to understand the world in which they live and being able to act on it in a thought-out and critical way. As a result, even if they must adapt to the realities and requirements of our times, primary and secondary school curricula should not fall into an exacerbated individualistic utilitarianism in their attempt to provide young generations with basic human and social education that is rich, diversified, and open. In sum, we must conceive the education of young people from an emancipatory perspective and it is our belief that the inter- and transdisciplinary approaches can significantly contribute to reaching this goal.

Acknowledgment

Our sincere thanks go to the Social Sciences and Humanities Research Council of Canada (SSHRC), which has funded our researches for 30 years, and to all colleagues who have collaborated with us and to all our former Master's and Ph.D. students who have been actively involved in our research activities and subsequent publications.

Introduction

Most people have an intuitive sense of what competence means and whom they consider to be acting competently, and they would like professionals or tradespeople to be competent in their areas of work. Given that (school) education is increasingly seen to be the means of preparing young people for the workplace, school curricula are expected to include the provision of the required competences. In this chapter, I give an overview of how the notion of competence has varied across different contexts and how its importance within curricula has changed over time. In doing so, I explore the role of a differentiated curriculum and the related topic of mass education, the connection between competence and assessment within the curriculum, the way in which the notion of competence is related to standards and how this in turn relates to the rising importance of accountability and monitoring in the education system, and I discuss the role of PISA as an example of the international prominence of competence. In the concluding section, I draw these strands together and I evaluate the place of competence in modern curricula.

The changing role of competences in the curriculum

There are numerous definitions of competence (and they can vary by context; see Carr, 1993). I do not intend to discuss their relative merits, but I would like to draw on Messick's (1984) description since it is interesting in the context of the curriculum:

Educational achievement essentially refers to what an individual knows and can do in a specified subject area as a consequence of instruction. Educational achievement should be distinguished from the closely related construct of competence, which refers to what an individual knows and can do in a subject area however that knowledge and skill is acquired, whether through instruction or experience or whatever. Like achievement, the term "competence" as used here refers to a continuous variable reflecting various degrees of proficiency rather than to its other common usage as a particular standard of adequate or sufficient performance. (p. 217)

Several aspects of this are worth noting. To begin with, competence here clearly is not reliant on teaching; instead, it is defined, in contradistinction to educational achievement, as a skill "however ... acquired". This does not preclude attaining competence as a result of schooling, but schooling is not necessary. This conceptualization of competence is to be found also, for example, in the UK's vocational education framework NVQ (National Vocational Qualification) where, in principle, certificates are to be conferred on the basis of demonstration of competence rather than on the basis of how much time had been spent in an educational institution (Wolf, 2000) (though problems arise in the implementation of this principle, but this is another matter). Another issue to highlight in Messick's definition is the distinction of competence (and educational achievement) from knowledge: competence relies on knowledge and goes beyond it since being able to act on one's knowledge is also required for a person to be deemed competent. A final point is the mention of standards which will be discussed below since, unlike in Messick's usage, competences actually are central to establishing standards in many contexts today.

Competence has not traditionally been a central goal of school teaching. Indeed, Hirst (1969) suggested that "[t]he objectives of education are surely certain developments of the pupil which are achieved in learning, and I suggest that these are all basically connected with the development of a rational mind." (p. 147) However, competence is not a new concept within formal education. Traditionally, it has been more commonly associated with vocational education and teacher education (Carr, 1993; Whitty and Willmott, 1991), having been used within teacher education as early as the 1920s by Ralph Tyler, as Norris (1991) points out.

Nowadays, it is one of the central features in general education curricula of many countries: schools are expected to produce competent individuals who are able to function in the workplace. Thus, the role of the education system is seen as to improve employability and to increase economic growth (for example, Wahlström and Sundberg, 2018a; Young, 2013), with a curriculum centered on competences being a means to foster such an improvement. Indeed, Wahlström and Sundberg (2018a) explicitly link these two phenomena: (1) the notion of employability as the aim of education and (2) the emergence of competence in the curriculum across many countries (p. 9). However, the nature of the link between education and economic growth is not as clear-cut as it is sometimes made out to be. It is clearly the case that in modern society, highly educated individuals on average tend to earn more than less highly educated ones, but it does not follow that expanding the time spent in education and/or changing the nature of education will result in economic growth and more prosperity for all (Wolf, 2002, 2004), nor that, for an individual, a high level of education is a guarantee of an attractive job (Bukodi and Goldthorpe, 2019).

In the next section, I explore further the notion of education as preparation for the workplace, discussing how this is linked to a differentiated curriculum as opposed to mass education for all, and what role competences play in this.

Competences in a differentiated curriculum and in mass education

As noted in the previous section, Hirst's view is that the overarching objective of education is the development of a rational mind in each child (Hirst, 1969), and that this applies regardless of the child's ability. Content and teaching methods may have to be adapted in various ways to make it possible to achieve this objective, but he evidently does not support the view that less able children should be taught mere skills (as opposed to knowledge and understanding) in order to function in a workplace where they are expected to carry out routine tasks. However, such a view has been expressed at least implicitly in various curricula. For example, Cooper (1985) analyses the history of the mathematics curriculum in England, discussing how in this subject (as in others), the curriculum has been differentiated according to school type and the associated type of career children of different abilities (and, frequently, different social backgrounds) can be expected to have. In such a curriculum, abstract knowledge and thinking is the preserve of the most able, and the others are to be taught skills which will enable them to function in simple jobs and in their daily lives. He quotes handbooks on Modern Schools (the most basic type of school in the old English tripartite system) which stress arithmetic at the expense of mathematics. Teachers he interviewed argued similarly that the role of the school for less able children was limited to providing them with the basic skills they could expect to need once they left school. The most highly academically selective grammar schools, by contrast, offered a mathematics curriculum which encouraged learning for its own sake as well as preparation for university study.

We can see that it is not a new idea for the school's role to be to prepare young people for the workplace. Historically, this link was made explicit only for the least educated groups who had to learn basic skills at school so that they would be able to cope with fairly low-level demands. But at the other end of the scale, while learning for its own sake was stressed, the most selective schools also prepared their pupils for their future careers, even if this was not their stated aim. The difference was in the type of career they were expected to pursue. Indeed, "learning for its own sake" does not necessarily have to mean that such learning has no purpose at all other than private enjoyment. Dore (1976, p. 8) describes why one of the reasons learning and knowledge may be appreciated is because they can enable the learner to do a better job. He contrasts "learning to *do* a job" with "learning to *get* a job" (emphasis in the original). The goal of learning in the former case is to acquire the knowledge and/or skills necessary to carry out a task in a satisfactory way; in the latter, learning is undertaken in order to gain a certificate which will then enable the bearer to obtain a job or access to a course of more advanced education (which can in turn lead to yet another certificate). In this latter situation, the learner may or may not be particularly interested in the actual content to be learned. Understood in this way, "learning for its own sake" is not just a way of describing the goal of learning; instead, it embodies a certain ideal way of living one's life (see also his discussion of the history of education and qualifications in England in his chapter 1).

Throughout the second half of the 20th century and into the 21st, alongside the expectation that education should prepare young people for the labor market, the role of the education system was seen by some parts of society as being a means of providing children of all backgrounds with equal opportunities. This is captured in the British Labour Party's slogan from the early 1960s which was "grammar schools for all", indicating that the type of education associated with advantageous subsequent careers available to former grammar school pupils should be made accessible for everyone. However, Cooper's analysis shows that this was not seen as feasible by many teachers, who assumed that the tripartite system reflected the fact that there really is a wide range of abilities and that not all children are equally well suited to studying the type of abstract content associated with the grammar school curriculum. By that time, England had moved to a largely comprehensive system, but the expectation that not all teaching content was equally suitable for children of different abilities remained in place nevertheless. This was also reflected in the way teaching was organized: many—if not most—comprehensive schools continue to employ some form of ability grouping at least for some subjects. The teaching content is differentiated within these groups (termed bands, streams or sets) according to the students' (assumed or measured) ability. More recently, Young (2013, p. 112) made a similar point noting that many teachers expect that only a minority of children would be able to benefit from a curriculum based on what he terms "powerful knowledge", i.e., the sort that makes access to privileged positions in society possible. Thus, differences still exist as to what type of content is taught to which children even in a notionally comprehensive system.

However, the expectation that it is the role of schools to provide a well qualified workforce is as strong as ever. According to Young (2013), the expansion of education seen in many countries from the end of the Second World War onwards is a result of

pressure from “global capitalism” (p. 106), and the face of education has changed accordingly. Thus, while it may be the case that children in developed countries generally have access to schooling for an extended period of time, this has not had the liberating effect proponents of increased access to education might have hoped it would have, because, in Young’s analysis, the demands arising from the economy and the pressure to acquire employability have all but replaced learning for its own sake and its “emancipatory role”. “Learning for its own sake” is “dismissed as elitist” when the goal of education is employability (p. 106, see also Rosenmund, 2007; Wolf, 2002).

Thus, while “knowledge for its own sake” has in fact always constituted a form of preparation for a child’s future career, the idea of acquiring such knowledge seems to have gone out of fashion altogether anyway, to be replaced by the proclaimed need for different forms of competence which will enable young people to participate in the modern labor market. Given the rapidly changing demands placed on modern employees, some policy-makers argue (as reported, e.g., by Rosenmund, 2007) that knowledge becomes obsolete too quickly and, therefore, schools should aim to offer more general competences instead which enable individuals to identify quickly any information that is needed to carry out a task, to locate this information and to apply it to the relevant context. This is a long way from Hirst’s (1969) notion of the development of a rational mind as the universal goal of schooling—he assumed that the acquisition of different types of knowledge was suited to this goal—though there are some parallels: in principle, a rational mind can be applied to any problem that is open to being solved rationally. Individuals with the capability to think rationally can transfer their knowledge to new contexts. But it seems that this is not currently pursued as a central goal of education (if it ever was). At the same time, as with older forms of a differentiated curriculum where “knowledge for its own sake” was taught to some and basic practical skills to others, young people today are likely to acquire different forms and levels of competence in the education system, as Cooper’s and Young’s analyses have shown. And, also as with older forms of a differentiated curriculum, they can expect to have different types of career. In that sense, employability is also differentiated: most young people who leave school are employable, but not necessarily in the same types of jobs.

Assessment

Rosenmund (2007, see previous section) analyzed the shift from a curriculum centered on knowledge to one focusing more on competences. Given that assessment is a central part of teaching and learning, and given that any assessment has to be suited to the content to be assessed, it may be necessary to develop new forms of assessment to match the new type of curricular content.

As we shall see, in the same way that the concept of competence moved from vocational education and teacher education into general education, so have ideas arising out of assessment of vocational education spread into general education. Specifically, the notion of standards, while, again, not a new concept in educational assessment, has gained more prominence in general education. It is discussed in the section “**Competence and standards**”. The section “**Standards as an instrument in accountability and monitoring performance**” focuses on how standards have been taken further: they are used not only to assess individual learning but also as an instrument in monitoring schools and educational systems.

Before I go on to discuss standards and monitoring, a more general point: It may be problematic to transfer concepts from one educational sphere to another. Young (2008) cautions against the simple import of principles which may be useful in vocational education into general education. To use learning outcomes as an indicator of a person’s competence, in his view, is more sensible in a vocational context where “in many cases it is important to know that someone is capable of competently carrying out specific tasks” (p. 123). But in general education, Young argues, goals cannot be expressed as “precisely specified outcomes”. Similarly, Pring (2004) discusses potential dangers arising from a reliance on skills only as the aim of education: these dangers partly stem from the fact that it is quite hard to define and measure skills appropriately, but also that many activities need knowledge and understanding as well as skills.

Competence and standards

Taken seriously, the principle to teach competences rather than, say, knowledge, does not just replace one form of educational content with another. Instead, competences are conceptualized in relation to some clearly defined task to be performed. Performance can then be assessed, though in the strictest sense, it cannot be graded since the underlying competence cannot be partially present—the individual either is or is not (yet) competent in relation to the task in hand. However, such a strict conceptualization may not be appropriate for most types of competence, and in the general education context, it is more common to refer to competence as a continuous variable which can be measured on a scale, as Messick (1984) has done (see section “**The changing role of competences in the curriculum**”). Nowadays, a combination of the two approaches may frequently be found: a widely applicable conceptualization is a threshold model, where grading on a scale is possible and appropriate, and where a minimum level on the scale has to be reached for someone to be considered competent.

In assessing competence, assessment criteria are derived directly from the task. Thus, competence-based assessment is a form of criterion-referenced assessment. That is, the assessment does not take the form of a comparison with the performance of other learners, as would be the case with norm-referenced assessment (Wolf, 2000). Instead, candidates are judged in relation to a standard, i.e., the threshold described above. Standards, then, are a key element in the assessment of the acquisition of competences. In certain areas, minimum standards are used to ensure that individuals act sufficiently competently in a given situation. An example are driving tests where safety considerations dictate that any driver should be competent enough so as not to endanger themselves

and other road users, though even in such a context, there may be a political component to standard-setting if there is a reason why not too few or not too many candidates should pass a competence test, thus introducing an element of norm-referencing. In the example of driving tests, it may not be politically viable if too many candidates fail their tests, making it hard for them to, for example, commute to work in areas with little public transport. Nevertheless, minimum standards can be very useful in certain contexts, though [Wolf \(2000\)](#) notes that there are dangers associated with them as well. One of them is that a minimum standard as defined in the curriculum may too easily be taken for the maximum standard when the curriculum is implemented. Thus, if a minimum standard is defined for a school subject, teachers may focus on ensuring that as many pupils as possible reach this minimum standard, something which in itself is desirable, but which may come at the expense of the learning of pupils who are able in principle to learn more than required by the minimum standard but who may not receive adequate support to do so.

There is clearly a close relationship between competences and standards. Given the provenance of the concept of competences in the vocational education context, this is unsurprising: assessment of competences in this context involved setting standards against which performance could be judged in order to determine whether the candidate could be deemed competent. Equally clearly, they are not the same thing, though this sometimes can appear to be the case when curriculum documents use the two terms as if they are interchangeable ([Glaesser, 2019](#)). In addition, the term standard is not always employed to mean a threshold separating competent from not-competent individuals. Instead, competence is measured on a continuous scale and several thresholds may be imposed after the fact to give several levels of competence. Such thresholds are not standards in the original sense of the term, since they are derived from the data rather than from theoretical conceptualizations of the underlying construct of competence.

Standards as an instrument in accountability and monitoring performance

The problem of setting minimum standards described in the previous section is exacerbated when not just the candidate's, but the teacher's or the school's performance is monitored using the minimum standard as a benchmark. For instance, the proportion of pupils achieving A* to C (i.e., top grades) in at least five subjects at GCSE (General Certificate of Secondary Education, a qualification taken by 16-year-olds in England and Wales) is a common measure of a school's performance, with the result that many teachers focus on pupils whose level of performance is around the C/D boundary, aiming to have as many as possible achieve at least a C in the actual exam. The result can be that pupils securely above (and well below) this borderline receive much less attention. Teaching to the test is a related and well-known problem: if the achievement of some standard is used to monitor teachers' or schools' performance, then the achievement of that standard becomes the overriding goal rather than the goal of imparting the associated knowledge or competence ([Pring, 2013](#)). The two goals may overlap, but not necessarily fully. This has become known as Goodhart's law: "As Charles Goodhart pointed out some years back, any measure used for control purposes becomes unreliable; so if qualifications are used for monitoring and funding, it is overwhelmingly likely that they will, in the process, become less reliable as sources of information on their holders' skills" ([Wolf, 2004](#), p. 329) (see also [Goldstein, 2020](#)). An example of such a situation is provided by [Schoenfeld \(2014\)](#) who describes how, as a result of the American No Child Left Behind Act (NCLB), high stakes tests were introduced on the basis of which students', teachers' and principals' fates might be decided, so that teachers focused on teaching whatever was demanded by the test. Referring to Hugh Burkhardt's phrase "What You Test Is What You Get" (see also Burkhardt's own chapter in the same volume, [Burkhardt, 2014](#)) Schoenfeld concludes that, in the case of high stakes tests, "testing drives the curriculum" (p. 60) rather than the other way round.

Thus, while it is desirable that the content of the curriculum determines what should be assessed in tests, the effect—arguably less desirably—also runs in the other direction: the way in which tests are designed and used can have a great impact on the curriculum as enacted, i.e., on the teaching itself (e.g., [Wolf, 2000](#), p. 86). For the reasons already discussed, this is problematic, since it is impossible to assess everything which may be regarded as a desirable outcome. Instead, tests are designed to be cost-effective and efficient with regard to time, covering content which is easy to administer and to score. But then teaching to the test may prevent pupils from acquiring other kinds of knowledge and competences which are also aims of the curriculum.

I will illustrate this point by drawing on another example, the case of foreign language learning: there is a wide range of goals associated with foreign language teaching and learning in schools. An obvious one is the acquisition of communicative competence, that is, the ability to communicate with other speakers of the foreign language. It is possible to define and operationalize this, something the Council of Europe has done in its Common European framework of reference for languages (CEFR, [Council of Europe/Conseil de l'Europe, 2001](#)) (for a discussion of the CEFR and its use of the concept of competence see [Glaesser, 2019](#)). The standards arising out of this framework can then in principle be transformed into suitable instruments of assessment. Incidentally, this is a good example of a continuous competence scale with (potentially) meaningful thresholds: there is a point below which there is no communicative competence—the person may know a few words of the language but is still unable to communicate—but above this point there are degrees of competence. For example, an individual may be able to communicate effectively but only in certain situations, or they can express only a limited range of views etc. In the CEFR, there are indeed several such thresholds, resulting in the levels A1 to C2, with clearly described competences an individual can be expected to have given performance at a particular level.

However, foreign language teaching and learning has far wider goals than the acquisition of communicative competence. Other aims are to gain an insight into a different culture including its literature and, possibly, an enhanced understanding of the human condition (e.g., [Paesani, 2018](#); [Paran, 2008](#)). Such things are harder to measure through standardized tests (e.g., [Paran, 2010](#)), and, accordingly, they cannot form part of the accountability framework. This potentially results in a neglect of such topics in the foreign language curriculum.

Accountability and monitoring may partly be a result of the move toward mass education discussed above: if an increased number of young people spend an increased amount of time in the education system, the cost of funding their education rises accordingly. Both politicians and the general public would like to be assured that the money is spent profitably. To this end, they aim to measure schools' performance in order to ensure that monetary input results in output in the form of competences, but, as discussed in this section, measurement of educational output is a complex undertaking with plenty of pitfalls. Such a monitoring approach to ensuring the quality of the education provided can be described as an output-oriented approach, where educational progress and success are measured against standards which are used as instruments of quality control. An input-oriented approach, by contrast, is one where the government aims to achieve high quality of the education system by focusing on teacher training, and by issuing curriculum guidelines and teaching materials. The actual results of teaching, that is, exam performance, dropout rates, and the like, are not the focus of attention for governments using an input-oriented approach. The two are not mutually exclusive, instruments from both forms of quality control are used by most governments, though the focus in recent years has shifted, as discussed in this section, towards more output control (e.g., Ertl, 2006; Glaesser, 2019).

Competences internationally: the PISA study

The Organisation for Economic Co-operation and Development (OECD) regularly conducts surveys of young people's proficiency in the subjects of reading, mathematics and science towards the end of their period of compulsory schooling. The OECD refers to these subjects as "domains of competence": "the survey measures students' proficiency in three foundational domains of competence—reading, mathematics and science" (OECD, 2019) and, indeed, the title of that publication, "What students know and can do" is identical to Messick's definition of both competence and educational achievement quoted in the section "**The changing role of competences in the curriculum**", with educational achievement being, according to Messick, the "consequence of instruction" and competence referring to "what an individual knows and can do ... however that knowledge and skill is acquired". Thus, in this definition, competences are not linked to any particular curriculum, and indeed, PISA does not set out to evaluate performance with respect to curricular content (Hopmann, 2008). Instead, it aims to assess how well the young people perform in relation to competences which they are expected to acquire in order to meet future demands in the workplace (OECD, 2019, p. 63). PISA is thus clearly concerned with competences, but since its focus is not on curricular content, a discussion of PISA may seem out of place in this chapter. However, it has an outsized influence on national curricula and policy-making, as I discuss in this section, and it does set out to compare the performance of different countries' education systems. It is therefore highly relevant to our discussion.

One of the ways in which PISA affects national debates on education and policy-making is how it assesses education systems' performance: its assessment is based solely on external indicators, and it relies on the concept of accountability as discussed in the previous section. Thus, it constitutes a purely output-oriented approach as a way of monitoring and improving performance; its claims concerning its ability to improve education systems are made on that basis alone, not on input-oriented measures. Wahlström (2018) concludes that, in the international context, PISA is a "key player" (p. 720) in the move towards monitoring of educational systems via an international comparison of students' performance. However, output-oriented policies preceded PISA, so it cannot be considered to have invented them, though it has contributed to the spread of the concept and its increased use (Lingard and Lewis, 2016). In that sense, it is both a symptom and a cause of such measures. With regard to its usefulness for reforming and improving educational systems, it is worth noting that PISA's sole focus on performance measures means that it is actually not particularly well suited to examining educational processes in any detail. It does not provide any evidence of what happens in the classroom and therefore no conclusions can be drawn regarding the success of particular teaching methods, and, while it is possible to break down PISA results by countries, schools systems, social background of individual students, gender etc., any differences in the results between the different groups and/or countries do not, in themselves, explain why such difference are found. But this lack of causal explanations does not prevent commentators from assuming that PISA results can tell us which features of particular education systems are responsible for good or bad performance, or—an example of a much debated topic—which education systems are better at ensuring social equality (however defined) (Wahlström, 2018). In fact, PISA results have been used to support opposing arguments, for example arguments both in favor of and against comprehensive schooling (Hopmann, 2008). Similarly, policy makers occasionally use PISA results to support a reform they were planning to carry out anyway, and, given its high public profile, PISA serves as a convenient reason, whether or not its results actually support the proposed reform (Lingard and Lewis, 2016; Tillmann et al., 2008).

In the preceding paragraph, I discussed PISA's influence on national educational systems through the accompanying drive towards monitoring and accountability (see also section "**Standards as an instrument in accountability and monitoring performance**"). Another way in which it exerts some influence is on curricular content directly. PISA describes itself as follows: "PISA is a triennial survey of 15-year-old students around the world that assesses the extent to which they have acquired key knowledge and skills essential for full participation in social and economic life." (OECD, 2019, p. 26) National curricula have taken on board this notion that schools are supposed to prepare young people for their future "participation in social and economic life" and therefore it is important to acquire competences needed later on through schooling. Germany, for example, introduced changes to its curriculum following the so-called PISA shock, i.e., the fact that the country's performance in the first round of PISA in 2000 was not as good as had been hoped and expected. These changes, which were made alongside changes to oversight and the focus of educational research, placed greater emphasis on competences than previously (Ertl, 2006). This is not a result of any teaching to the test,

which would be hard to do in the case of PISA since there is no published practice material. In addition, neither teachers nor individual pupils are held directly to account on the basis of their PISA results, so, for them, there is no direct incentive to achieve highly on PISA. Instead, the focus on competences arises directly out of changes to the curriculum (Glaesser, 2019; Küster, 2016; Prenzel et al., 2015; Stanat, 2018). Similar changes have taken place in Austria (Hopmann, 2008) and in Australia (via the NAPLAN scheme, see Lingard and Lewis, 2016, p. 396), for example. Without linking this directly to PISA (though see Hopmann, 2008, p. 435), Wahlström and Sundberg (2018b) describe how the curricula in Nordic countries have also been changing in recent years to place greater emphasis on the competences associated with employability. They do note, however, that in recent years, there has been “curriculum convergence” globally (p. 4) and that “another area of convergence, and perhaps a stronger one today, concerns the use and development of accountability in output measures and standardized assessments in international knowledge tests like the Programme for International Student Assessment (PISA).”

In summary, PISA’s focus on the type of competences expected to improve participation in social and economic life has influenced national curricula both through changes to curricular content directly and through the greater use of accountability and output-based policies in many national educational systems.

Conclusion

As noted above, Messick (1984) implied that competences may be acquired anywhere, inside as well as outside the classroom. However, the concept has become central to school curricula. Writing as early as 1991, Norris (1991) commented: “Everybody is talking about competence. [...] Words like ‘competence’ and ‘standards’ are good words, modern words; everybody is for standards and everyone is against incompetence.” (p. 331) The discussion in this chapter has shown that this focus on competences has resulted in various developments, some of which may be more welcome than others.

The decision on whether to plan school curricula which include competences to be taught cannot be based on empirical evidence alone: “But, before considering the nature of evidence, it is worth saying that public policy decisions are, and should be, influenced by considerations beyond the research evidence, such as priorities, feasibility, acceptability, ethics and so on. All of these will involve judgements, typically subjective ones” (Goldstein, 2020, p. 38). In the case of planning curricula, an example of choices which have to be made on the basis of such considerations is whether content which may be regarded as “knowledge for its own sake” is so valuable that it should be taught, regardless of whether or not it can be expected to have any immediate benefits apart from, hopefully, enjoyment of the content. More generally, decisions have to be made concerning what the aims of any curriculum should be, whether economic aims such as employability trump everything else or whether different kinds of aims are considered important, too. Budgetary constraints may also play a part in designing curricula. In addition, certain questions are very hard if not impossible to answer empirically. Assuming that employability is a key goal, an empirical test of whether a curriculum is suitable for achieving this goal would have to take account of what demands will be made by the labor market around twenty years later. There are ways of modeling this, but there will still be great uncertainty. It is also quite difficult to determine, empirically, what suitable teaching methods and content look like with regard to achieving a particular goal. Even if it was clear what effective teaching looks like—something that is actually very hard to determine, though some helpful frameworks exist (e.g., Coe et al., 2014)—it would not necessarily be straightforward to implement it. A curriculum not only has to be designed but also enacted (e.g., Burkhardt, 2014). Thus, a focus on both content and implementation is necessary. The wider political context should also be considered: what reasons might politicians, policy makers and various interest groups have for wanting to include competences in the curriculum, or indeed for not wanting to include them? What unintended consequences might there be, for example with regard to assessment and standards (see section “Standards as an instrument in accountability and monitoring performance”)? Some of the questions raised in this paragraph, rather than being amenable to empirical analysis, call for theoretical or philosophical analysis.

There are some reasons to argue that caution may be required in incorporating competences into curricula. Some potential pitfalls have been discussed in this chapter. On differentiation, I would like to stress that there is likely to be no panacea to the problem of unequal opportunities and outcomes in the education system and the labor market. Talent and privilege greatly affect career prospects, and it seems unlikely that competence-based curricula can change this. With regard to competence-based assessment and standard-based monitoring of individual pupils, schools and education systems, unintended consequences have already become apparent, and they have been well documented by numerous authors (e.g., Ball, 2008; Hopmann, 2008; Lingard and Lewis, 2016; Münch, 2012; Pring, 2013; Ravitch, 2010).

A final comment on the link between a competence-based curriculum and the employability it is expected to produce: given that the link between educational and economic growth is much less clear-cut than we are sometimes led to believe (Wolf, 2002, 2004) (see also Bukodi and Goldthorpe, 2019), more caution would be in order concerning the expectations placed on the education system with regard to its contribution to employability. Obviously, schools play an enormously important part in preparing young people for the work place, but it is less clear exactly how they do this, and what particular types of content are most likely to achieve this aim (not least because employability can mean different things—see the point regarding “differentiated employability” at the end of section “Competences in a differentiated curriculum and in mass education” above). Therefore, more theoretical analyses and more empirical research are in order if we wish to obtain a clearer picture of what the curriculum can contribute to the various aims that have been entrusted to it, while at the same time more humility might be required in the claims made with regard to what it can achieve.

Acknowledgment

My thanks go to Barry Cooper for his very helpful comments on this chapter.

Curriculum is a complicated concept and is defined in different ways by scholars who are working in different countries and regions, in different academic fields, and who have different research purposes (Aoki, 1980/2005; Jung and Pinar, 2015). As a result, the concept is elastic and multifaceted; it has been described as involving a “cacophony of voices” (Pinar et al., 1995). As in other academic fields, discourse has advanced the field of curriculum studies, leading to the inclusion of new concepts such as hidden curriculum, null curriculum, etc. This chapter presents another concept, shadow curriculum, which has emerged from the international phenomenon of private supplementary tutoring, also known as shadow education. The following discussion explores the aspects of shadow education that have led to the need for shadow curriculum. It also reviews the history of cognate concepts that are related to shadow education, presents a broad definition of the phenomenon, and concludes with areas for future research within the field of curriculum studies.

Need for a new definition: shadow curriculum

Why do we need to develop a new curricular concept? The following discussion explores four important and interrelated elements related to the worldwide phenomenon of shadow education and how these have led to the need for a new concept in the field of curriculum studies.

First, many students now learn in shadow education spaces for both remedial and accelerated learning. Historically, shadow education has been prominent in some East Asian countries such as South Korea, Japan, Hong Kong, Taiwan, and Singapore (Bray, 2007[1999], 2017; Dawson, 2010; Entrich, 2017; Kim, 2016; Mori and Baker, 2010). It has now expanded to become a worldwide phenomenon. Since the beginning of the 21st century, it has emerged in many countries including Canada (Aurini and Davies, 2004), China (Zhang and Bray, 2017), Egypt (Hartmann, 2013), England (Jerrim, 2017), Australia (Watson, 2008), and many others in South Asia, Southern and Western Europe, North Africa, and South America (see Bray and Kwo, 2014; Kim and Jung, 2019a,b). Specifically, Jerrim (2017) reported that approximately one-third of students aged 11–16 years in England and Wales engaged in shadow education. Notably, he found that half of the students in London accessed private tutoring, depending on grades, regions, and social-economic status of families. Jerrim also found that 11th graders in England spend on average 9.5 h per week in private tutoring, and that this is significantly less than students in 12 other European countries. Aurini and Davies (2004) found that in the Canadian context, shadow education was school-like in terms of organizational structure, curriculum, and participation rates. They found that as of 2002, 24% of Ontario students were taking tutoring classes, and that the tutoring business had increased by 200–500% in major Canadian cities during the previous 30 years. Sweden, along with other Nordic countries, has experienced rapid growth in the market for private supplementary tutoring (Bouakaz, 2012; Forsberg et al., 2020; Hallsén and Karlsson, 2019).

Second, research has demonstrated that shadow education serves various functions to ensure academic success, including supporting student learning in schools, improving academic performance, and obtaining admission to a prestigious schools or universities. While the findings have yielded some inconsistent results, they generally suggest that shadow education significantly improves academic achievement of specific groups of students (see Dang and Rogers, 2008; Choi and Park, 2016), and that the effects are generally positive (Buchmann et al., 2010; Mischo and Haag, 2002; Davis et al., 2011; Brand and Xie, 2010; Kim and

Jung, 2019a,b; OECD, 2012; Carr and Wang, 2015; Entrich, 2014; Askew et al., 2010). More specifically, research has demonstrated that shadow education can help students improve their scores on university examinations such as the SAT and KSAT (Byun and Park, 2012; Appelrouth et al., 2017). Hu et al. (2015) reported that supplementary math tutoring had significant and positive effects on math scores among students in Hong Kong, Japan, South Korea, and Shanghai. Byun and Park (2012) found that East Asian students in the United States were more likely to take SAT preparation courses provided by shadow education services and that these improved their test scores. Appelrouth et al. (2017) found that individual tutoring was more effective than group tutoring for students in the United States. In the South Korean context, Hyung Jai Choi (2008) reported a positive relationship between private tutoring and college admission. Jung-Ho Yang (2012) also investigated the relationship between shadow education participation and the likelihood of university entrance; an analysis involving multinomial logistic regression revealed a strong relationship between private tutoring and admission to a four-year university. Kim (2016) collected in-depth narratives of how Korean students learn in shadow education to increase and/or maintain school grades and eventually obtain college admission. Although some scholars have reported that the effects of shadow education differ depending on the characteristics of students (Hof, 2014; Zhang, 2013), research appears to indicate that students in most countries can benefit from shadow education.

Third, with the expansion of shadow education, students who are simultaneously in and out of schooling are constructing a new culture of learning (Williams, 2013; Jung, 2018; Kim et al., 2018). This transboundary culture of learning is emerging as students crisscross the spatial, temporal, institutional, and curricular boundaries between public schooling and shadow education (Kim and Jung, 2019). Within this new culture, students are active agents who decide what, when, where they learn, and from whom. This has been weakening the status and authority of school curriculum; one scholar argued that the new culture of learning is a form of attack on institutionalized schooling and a commitment to self-determined learning that “reanimates the countercultural deschooling agenda” (Williams, 2013, p. 42). Shadow education provides more options for learning, allowing students and parents to be important decision-making agents in terms of curriculum. Students have traditionally been expected to learn the materials they are presented with in school, and this is still the case in many countries, but the emergence and expansion of shadow education is dramatically changing the ecology of education, eroding the authority of school curriculum and making students key decision-makers in their own learning.

Fourth, although private tutoring currently coexists with public education, it historically pre-dates it. Worldwide, people learned from private tutors long before public education systems emerged. The sophists in Ancient Greece and Rome could be described as freelance or personal teachers of philosophy who were “very strictly private tutors with no official standing whatsoever” (Winter, 1997, p. 25). Gordon (1988) traced the history of tutoring from Ancient Greece to the United States. Tutors have been called sophists, paidagogós, tutela, thetores, domi, fori, pedagogue, pedisequis, comes, custos, rector, governor, and governess. In Medieval Europe they were sometimes called escalate or theological. Gordon argued that in the 20th Century, American public education became almost exclusively a school experience, with tutorial philosophies and methods forgotten or quietly absorbed by tax-supported public schools, but that the American progressive education movement continued to embrace the concepts of individual differences and child-centered education first proposed by philosopher-tutors like Erasmus, Elyot, Vives, Thomas More, Locke, Fenelon, Rousseau, and others. Gordon also highlighted the roles played by tutors in the ‘visiting teacher movement’ during the ‘domestic education’ period in the 1920s in the United States and in many educational capacities throughout modern Great Britain; tens of thousands of teachers in England supplemented their income through private tutoring, but in 1985, when Gordon was conducting his research, this activity remained highly secretive for tutors, children, and parents. In English, shadow education is usually called private supplementary tutoring; it is referred to as private tuition and coaching in Bangladesh, India, and Pakistan; juku in Japan; hakwons and sagyoyuk in South Korea; and buxiban in Taiwan. In Ireland, shadow education might be called fosterage; in Italy, courtesy education; and in Germany, wohnstübenerziehung, erziehungskunstler, or Nachhilfe (Bray, 2007(1999); Kim and Jung, 2019a,b).

Overall, the worldwide phenomenon of shadow education cannot be ignored by curriculum studies scholars. The next section explores the new concept of shadow curriculum, which curriculum studies scholars can apply in future research.

Evolution of the concept

This section focuses on academic discourse related to K-12 educational contexts, where shadow education is conceived as private tutoring that supplements public education. For example, the term ‘shadow education system’ has been used to describe worker education contexts, but this is beyond the scope of this discussion (Wirtz, 1979; Craig and Evers, 1982).

In the 1970s and 1980s, scholars, educators, and policymakers were urged to pay attention to the phenomenon of shadow education. In his 1976 book *The Diploma Disease*, Ronald Dore critiqued the failing public schooling system for being geared toward “mere qualification-earning” for the modernized job markets in England, Japan, Sri Lanka, and Kenya. He noted that supplementary tutoring was an important element of this, helping students pass examinations to earn qualifications. In 1976, the Japanese government conducted a survey to investigate shadow education (Mori and Baker, 2010). This inspired more work including Rohlen’s books *The Juku Phenomenon: An Exploratory Essay* (1980) and *Japan’s High Schools* (1983), in which Rohlen referred to shadow education as the pursuit of educational advantage among middle-class families. In the South Korean context, Jung-Han Kim (1985) wrote on the intense home-visit form of private tutoring (gwaoe) used to prepare for university entrance examinations.

In the 1990s, scholars made efforts to develop the terms “shadow education” and “private supplementary tutoring” as academic concepts. de Silva et al. (1991) used the term “private supplementary tutoring” in their book *Extra-school Instruction, Social Equity and*

Educational Quality (Sri Lanka). Marimuthu et al. (1991) were the first to use the shadow metaphor in their Malaysian study. The next year, Stevenson and Baker (1992) defined shadow education as “a set of educational activities that occur outside formal schooling and are designed to enhance the student’s formal school career” (p. 1639). Bray popularized the term “shadow education” in his 1999 book *The Shadow Education System: Private Tutoring and Its Implications for Planners*.

Since 2000, more scholars have conceived of shadow education as an international phenomenon. Bray 2007(1999) book was the first to incorporate data from many countries and provided a comprehensive picture of shadow education in the international context. It inspired cross-national comparisons in terms of the intensity of shadow education, educational inequality, and government policies. Baker et al. (2001) extended the discourse in their book *Worldwide Shadow Education: Outside-School Learning, Institutional Quality of Schooling, and Cross-National Mathematics Achievement*; they argued that shadow education is prevalent worldwide and described the strategies and characteristics used in different countries and regions. Since then, many researchers have framed shadow education as a common international phenomenon (Ireson, 2004; Silova et al., 2006; Bray and Lykins, 2012; Manzon and Areepattamannil, 2014; Entrich, 2017).

Until recently, the concept of shadow education has mainly been defined and used in academic fields including comparative education (Mori and Baker, 2010; Ventura and Jang, 2010), education and policy (Bray and Kwo, 2014; de Castro and de Guzman, 2014; Ireson, 2004; Park et al., 2016), sociology of education (Byun, 2010; Yamamoto and Brinton, 2010), education and economics (Entrich, 2014; Zhang, 2013), and lifelong education (Ozaki, 2015). Few scholars have tried to define shadow education from the perspective of curriculum studies. In *Shadow Education: Evolution Flaws and Further Development of the Term*, Malik (2017) pointed out the ambiguity of the concept of shadow education and identified subcategories including shadow teaching, shadow curriculum, and prerecorded academic aids. These subcategories are helpful for revealing various possible, and understudied, research topics, but we argue that Malik’s use of the term “curriculum” is limiting. Malik defined curriculum as “textual” and conceived it as a static entity of materials. In reality, a curriculum is neither static nor singular (Pinar et al., 1995). The next section presents a new concept for inclusion in the field of curriculum studies: shadow curriculum.

Defining shadow curriculum

The following discussion draws from existing terminologies, definitions, and characteristics of shadow education, beginning with the commonly accepted characterization of shadow education (Bray, 2007(1999)). Next, we draw from our extensive literature review and our own fieldwork to present four main characteristics of shadow education. Finally, based on these findings, we present a definition of shadow curriculum.

The characteristics of shadow education

Shadow education can be generally defined as “private supplementary tutoring in academic subjects beyond the hours of mainstream formal schooling” (Bray, 2006, p. 515; also see e.g., Marimuthu et al., 1991; Stevenson and Baker, 1992; Silova et al., 2006). It has five general forms: private tutoring institute, home-visit private tutoring, Internet-based tutoring, subscribed learning program, and academic after-school program (Kim and Jung, 2019a,b).

According to Bray (2007[1999]), shadow education involves three main characteristics: supplementation, privateness, and academic subjects. “Supplementation” refers to both remediation and acceleration for student learning in mainstream schooling. In other words, shadow education can help low-achieving students catch up and help high-achieving students advance faster and more (Carr and Wang, 2015; Cho, 2015; Entrich, 2014; Kim and Jung, 2019a,b).

“Privateness” refers to funding source: parents/families pay tuition to shadow education providers such as educational personnel and companies (Stevenson and Baker, 1992; Bray, 2007[1999]; Malik, 2017; Kim, 2016). Importantly, this characteristic excludes any form of schooling, both public and private—including home-schooling funded and regulated by governments. It also excludes individual or group self-directed study at home, as this does not involve an instructor. It also excludes various available learning sources such as online videos uploaded by the Kan Academy or individual creators as they do not specifically target registered students—however, these may be components of shadow education when they are intentionally assigned to specific students by shadow education instructors. Many scholars have focused on this characteristic of shadow education because it is generally seen as exacerbating educational inequality (Melot, 2007; Klemm and Klemm, 2010; Majumdar, 2014).

“Academic subjects” refers to the explicit objective and contents of shadow education. Shadow education is in general intended to ensure academic success by helping students improve their scores on school examinations and obtaining admission to a university of choice (Lee, 2007; Yamamoto and Brinton, 2010). For this reason, the most popular subjects in shadow education are language arts, mathematics, English (and other foreign languages), and science (see Bray and Lykins, 2012; Kim, 2016; Kim and Jung, 2019a,b).

These three characteristics are important elements of shadow education, but Bray’s analysis was incomplete. We argue that shadow education involves a fourth characteristic: individualness. “Individualness” refers to students seeking learning opportunities that best meet their individual needs, educational purposes, and level of learning (Bray, 2007[1999]; Ozaki, 2015; Kim, 2016; Entrich, 2017; Malik, 2017; Kim and Jung, 2019a,b). In most countries, mainstream education is based on the values of “education for all” and “education for equality” (Mori and Baker, 2010; Bray, 2017). As a result, its instruction, programs, and evaluations are usually age-based to make education equal and fair. In contrast, shadow education is delivered based on each

student's intellectual abilities, needs, interests, and learning speed (Ozaki, 2015; Kim, 2016; Entrich, 2017; Kim and Jung, 2019a,b)—and shadow education businesses only profit when they meet the needs of individual customers (Bray, 2007 [1999]; Kim 2016; Malik, 2017).

Shadow curriculum: definition and characteristics

Building on the previous discussion, we can broadly define shadow curriculum as: supplementary curriculum out of schooling provided by educational business industries for academic success of individual students in formal education.

Shadow curriculum has four distinctive characteristics that differentiate it, at least in part, from curriculum used in mainstream education. The following sections explore these characteristics, based on our extensive literature review and our own field research in South Korea.

Focusing on the academic success of students in schooling

The first characteristic of shadow curriculum is that its primary focus is to help students achieve academic success. This is the main reason that students access shadow education (Mori and Baker, 2010; Stevenson and Baker, 1992; Silova et al., 2006; Bray, 2007(1999); Byun and Park, 2012; Byun, 2010; Kim, 2016; Zhang and Bray, 2017; Entrich, 2018). In most countries, school curricula are designed to promote holistic development in students by balancing intellectual, affective, and psychomotor development. In contrast, shadow curriculum is oriented toward academic success, and especially improving scores on university admissions examinations (Kim, 2016; Ozaki, 2015; Stevenson and Baker, 1992). In this respect, it is developed to be goal-specific and task-oriented for a specific test or improve a grade in a key course (Aurini and Davies, 2004; Harnisch, 1994; Kim, 2016; Kim and Kim, 2012; 2015; Stevenson and Baker, 1992; Yamamoto and Brinton, 2010). Many studies have focused on this element of shadow education in Japan (Stevenson and Baker, 1992), where intense engagement in *juku* has been linked with university admission and overall future success in life (Ozaki, 2015; Harnisch, 1994). Similar findings have been reported in South Korea, where shadow curriculum is highly oriented toward guiding students to prepare for school examinations and the College Scholastic Ability Test (Kim, 2016; Kim and Jung, 2019a,b). Aurini and Davies (2004) found that shadow education in Canada also tends to be goal-specific and task-oriented, usually to pass an upcoming test or improve a grade in a key course. Another example is Finland, which is known for its excellent education system. Kosunen (2018) recently explored the emerging processes of hidden privatization in education and found that tutoring in preparatory courses for the competitive university entrance examinations in Finland could be interpreted as a form of private education as it “functions alongside the public education system, the aim being to enhance the position of clients by facilitating access to higher education ... while collecting tuition fees” (p. 67).

Fulfilling the academic needs and abilities of individual students

Shadow curriculum provides individualized, personalized, and differentiated learning specific to each student (Medway, 1995). This kind of education was common before the emergence of public schooling, based on tutorial philosophies and methods (Gordon, 1988). Now, most mainstream schools teach students the same content as a group, at the same time, using the same methods. Some schools have made efforts at individualized learning, but students tend to be more motivated by private tutoring (Silova, 2010). This is particularly true in South Korea, where many students rely on *hakwon* education to achieve their goals because public schooling does not meet their academic needs (Kim, 2016)—and shadow curriculum actively and aggressively addresses consumer need (Kim, 2016; Kim and Kim, 2012; 2015; Mawer, 2015). In some countries such as Japan, Australia, and South Korea, the public education system provides vouchers to students whose needs are not met in schooling so that they get extra academic support from shadow curriculum providers (Dawson, 2010; Kim and Jung, 2019a,b). Generally, students and their parents seek shadow education because public education systems are less able to provide individualized learning (Bray, 2007(1999); Bray and Kwo, 2014; Kim, 2016; Ozaki, 2015; Park et al., 2016).

Shadow curriculum providers respond to this need (Bray, 2007(1999); also see Bray and Kwo, 2014; Kim, 2016; Kim and Jung, 2019a,b; Entrich, 2017). They may use techniques such as one-to-one tutoring (Bray, 2009). In South Korea, many *hakwons* use ability grouping, differentiated instruction, tailored curricular programs, and counseling informed by portfolios, learning diaries, university exam preparation schedules, and accumulative evaluations (Kim, 2016). In Japan, *hingaku*, *hoshu juku*, and *juku* that specialize in *kobetsu shido*, a type of *juku* that is focused on individual instruction, provide highly individualized instruction for both academic study and more general guidance (Mawer, 2015). Internet-based private tutoring also provides highly personalized content with many choices in terms of subject areas, levels of courses, materials to be used, and teaching methods (Kim and Jung, 2019a,b; Kim, 2016; Park et al., 2016; Ventura and Jang, 2010). In contrast to the curriculum provided in public schools, where students are assigned teachers and learning materials, students engaging with shadow curriculum can manage their own learning by selecting specific instructors, course content, learning speed, as well as where and when to study.

Providing differentiated content based on the amount of tuition

The third characteristic of shadow curriculum is tuition, which is generally not a part of mainstream education. Families pay to access shadow curriculum, and in general, higher tuition will ensure a smaller teacher-student ratio, more frequent sessions, more

qualified instructors, and better curricular materials (Kim and Jung, 2019a,b). Wealthy families are more able to live near public schools with better quality education, and may even move to certain areas (e.g., Gangnam in Seoul) to better their children's education (Kim, 2016; Park et al., 2015). However, parental investment in shadow curriculum tends to function more powerfully—and much more quickly. One-to-one tutoring, which is generally considered the most personalized, is usually the most expensive (Bray and Kwo, 2014; Kim, 2016). Internet-based tutoring is the most reasonably priced, but it becomes more expensive if a student needs more courses or individual services.

Shadow curriculum can be considered a form of positional good because it is highly subject to a family's socio-economic status (Halliday, 2016). Students from wealthy families are more likely to access—and benefit from—shadow curriculum than their less resource-rich counterparts (Bray and Kwok, 2003; Byun and Kim, 2008; Dang, 2007; Kim, 2016; Rowley et al., 2020). Empirical research has demonstrated that shadow education can reproduce and/or strengthen educational inequality (Park et al., 2015; Sun and Braeye, 2012; Lee et al., 2010), and many scholars have criticized it for this reason (Dawson, 2010; Halliday, 2016). For example, researchers have documented the positive relation between familial investment and entrance rates to prestigious schools in Korea (Kim, 2015; Kim and Park, 2010).

However, Rowley et al. (2020) analyzed the OECD Program for International Student Assessment (PISA) results of students from wealthy countries and concluded that scores are not necessarily affected by socio-economic status. Additionally, some researchers have found that shadow curriculum can actually equalize educational opportunity by providing extra support to disadvantaged children (Aurini et al., 2013; Bray, 2009; Entrich, 2017). Overall, the issue of whether shadow curriculum contributes to educational inequality is far more complex than it first seems.

Increasing the competitive nature of education

The fourth main characteristic of shadow curriculum is that it perpetuates the idea of education as competition (Jung, 2014, 2016). Students work to obtain the best grades and test results, and shadow education is contributing to intense competition (Halliday, 2016; Kim, 2003; Kim and Kim, 2012, 2015; Lee, 2007; Mawer, 2015). High-achieving students are much more likely to engage in shadow education because they want to maintain their superior position in terms of academic achievement (Toyama-Bialke, 1997; Bray, 2007[1999]; Kim, 2016; Tseng, 1998). Under this kind of intense competition, students tend to consider other students as rivals to defeat, and to be preoccupied with test scores and school grades rather than focusing on the intrinsic value of learning (Kim, 2016; Park et al., 2015; Zhang, 2013). Halliday (2016) argued that this can lead to a kind of “educational arms race” at the expense of educational development, noting that students become vulnerable when competition comes before the intrinsic value of learning. Taubman (2010) came to similar conclusions in his discussion about the discourse of standards and accountability in education, arguing that teaching and learning for numbers extracted from students, teachers, and schools makes students vulnerable to centers of control while providing the illusion of objective accountability and meritocracy. Overall, although competition is an increasingly important element of education in many countries, it should not be the primary or only component of student learning culture. As far as the role of shadow curriculum is concerned, it would be hard for shadow curriculum free from the accusation that many scholars criticized.

Shadow curriculum for future curriculum studies

This section presents areas for future research in the field of curriculum studies. Certain elements of shadow education remain largely understudied (Zhang and Xie, 2016), especially within the field of curriculum studies (Kim and Jung, 2019a,b). The advantages of shadow curriculum are largely unknown and require rigorous investigation. Most discourse related to shadow education has focused on negative aspects of its practices (Bray, 2007[1999]), especially the increased workload for students (Yamamoto and Brinton, 2010) and the financial burden for families (Park et al., 2016, 2015) that may also perpetuate educational inequalities (Bray and Kwo, 2014; Burch, 2009; Stevenson and Baker, 1992). More recently, some scholars have begun to focus on the advantages of shadow education. For example, Hajar (2018) found that in England, private tutoring not only provides tangible benefits such as academic achievement but also intangible benefits among students by boosting their self-esteem, confidence, and interest in learning. Other scholars have reported that shadow education provides similar benefits to student wellbeing (Jung and Jung, 2019; Ozaki, 2015). Still, the advantages of shadow curriculum remain largely unknown, possibly because of the power dynamic between mainstream education and shadow education. More research is needed to explore issues such as these. Shadow curriculum involves innovative practices. Although it “shadows” mainstream curriculum, it is not tightly controlled by governments, and its reach continues to expand; for example, advances in technology have led to rapid expansion of Internet-based private tutoring.

The power dynamic between schooling and shadow education is an important issue for further research. Shadow education has been framed as subordinate or inferior to public education (Bray, 1999; de Silva et al., 1991; Marimuthu et al., 1991) or as an “exotic” cultural practice in East Asian nations (Mori and Baker, 2010). This kind of framing is related to the long-standing prioritization of public schooling within the field of curriculum studies. This stance was rationalized based on the almost exclusive emphasis on the “backwash effects” of shadow education that have led to educational policies intended to control or suppress shadow education (Bray and Kwo, 2014; Doherty and Dooley, 2018; Kim and Jung, 2019a,b). However, this issue is far more complex than it first appears. Shadow curriculum offers what public schools do not, including remedial instruction (Roesgaard,

2006). In this way, shadow curriculum can actually reduce inequality in educational opportunities (Kim, 2016; Mori, 2012; Entrich, 2014; Kim and Jung, 2019a,b; Tsuneyoshi, 2001; Dawson, 2010). Shadow curriculum can also play an important role in preserving ethnicity, cultures, and languages (Sun and Braeye, 2012; Zhou and Kim, 2006; Kim and Jung, 2019a,b). More research is needed to explore why students are drawn to private tutors more than public school teachers (Paramita, 2014), why and how the phenomenon of “inverted roles” has emerged between schools and shadow education institutes (Yang and Kim, 2010), and why and how shadow education in some countries has become school-like (Aurini and Davies, 2004).

Another issue for future research is how shadow curriculum affects school curriculum, and how school teachers teach. Some research suggests that shadow education can lead to corruption among teachers; a study in Vietnam revealed some teachers provide tutoring classes for students for whom they are already responsible, and many exclusively disclose examination questions to the tutored students (Vu et al., 2011). Similar findings have been reported in Cambodia (EIC et al., 2006) and Central Asia and the Caucasus (Silova, 2010). On the other hand, student participation in shadow curriculum also affects school teachers. Many teachers are facing more challenges as more students access shadow education. Teachers in South Korea report that many students do not pay attention in class because they have already learned the targeted contents in shadow education (Kim and Jung, 2019a,b). In Japan, up to 30% of junior high-school students reportedly sleep through class (Hattori et al., 2010), often due to their attending juku (Ozaki, 2015). Some countries have introduced policies regulating shadow education (Bray & Kwo, 2014). More research is needed to explore how shadow curriculum influences school curriculum and instruction, and this should include different contexts and involve diverse research foci.

Another area for further research is transboundary curriculum. Some scholars have argued that technological innovations in education have led to a countercultural “deschooling” agenda that is against institutionalized schooling and assembly-line learning, and instead promotes self-determined learning through informal networks and community bonds (Williams, 2013). Student learning has become increasingly flexible, and the line between schooling and shadow curriculum is becoming increasingly blurry. Schools and school teachers are being decentered as the sole educational authorities as student learning is happening “in and beyond school walls” (Park et al., 2016), “physical and cyber learning spaces” (Ventura and Jang, 2010; Williams, 2013), and “official and nonofficial curricular programs and materials” (Kim and Jung, 2019a,b). In this respect, curriculum scholars need to explore both mainstream curriculum and shadow curriculum, specifically how students learn in complex and blurry new ways. It is vital that we understand how shadow curriculum fits into the whole picture of student achievement. One way to do this is through analysis of international comparison test results, e.g., PISA and TIMSS scores. One report (OECD, 2012) has already recognized the importance of shadow curriculum for students’ achievement, but it provides limited data. More comprehensive data collection and analysis will help reveal the quality of student learning in different learning contexts and to what extent their learning in shadow curriculum affects their achievement. PISA or TIMSS could aid this kind of research by develop new evaluation designs to assess how, where, what, and with whom students learn.

Conclusion

Educational scholars can no longer ignore shadow education. It has become an important component of the ecology of education worldwide, and should no longer being considered an intruder or “invasive species” (Bray and Kobakhidze, 2015). Instead of being framed as having only negative effects on students, families, and mainstream education, the phenomenon deserves scholarly attention and acceptance. More research on shadow curriculum will greatly broaden our understanding of the phenomenon, and break new theoretical ground in the field of curriculum studies. The power dynamic between public education and shadow education is complex, and should not be limited to the dominant antagonistic stance toward shadow education (Takeda, 2005; Ozaki, 2015; Kim and Jung, 2019). We hope that as an initial academic effort in curriculum studies, our new concept of shadow curriculum opens intellectual space for more nuanced and complicated conversations.

Introduction

In 1956, Swedish author and Nobel laureate in literature Harry Martinson (1998) published a book-length science fiction poem about a spaceship, *Aniara*. The story recounts that humanity has made the Earth uninhabitable through pollution and nuclear war. Today, the poem might be read as an anticipation of the Anthropocene's predicament—not only the story's plotline but also its depiction of how humans gain a god-like power to cross the boundaries of the planet, but lost control over the mechanisms and are now endangering the life-supporting systems of the planet (Rockström et al., 2009). The eponymous spaceship, the *Aniara*, begins to shuttle refugees to a new colony on Mars, but an accident veers the spaceship off course, destroying its steering ability. Slowly, the passengers start to realize that they are trapped on a relentless path into infinite space. This insight comes in phases, and the passengers react based on their different positions and experiences. At first, everyday routines continue, along with the trust that the ship's engineers will restore the steering technology. Meanwhile, Miman, a kind of interactive computer, offers solace through nostalgic images of the lost Earth. Soon, they enter a more nihilistic phase, and many passengers start living as if each day were their last. Hedonists clash with groups harboring fundamentalist ideals about penance, who believe that strict rituals will appease a power greater than themselves. Finally, the passengers succumb to apathy.

According to Mills (2000), dystopias are a sort of a sociological imagination of the fears of one's own time. As such, *Aniara* can be read as an allegory for the atomic bomb anxieties during the Cold War period and, for contemporary readers, the fright of an ecological collapse. Beyond these present threats, the poem also expresses a more subtle ambivalence toward the past and the future. As Koselleck (2004) notes, expectations of a crisis seem inherent to historical consciousness. In premodern times, the apocalypse was the final crisis, and it was unavoidable. Totally submissive to the will of God or gods, humans could do little to intervene. In modernity, crises have specific causes that bring possibilities for change: crises should be overcome, and they trigger evolution. While the brutal catastrophes of the twentieth century undermined the expectations that carried the European Enlightenment toward a future that was open to refinement (Hartog, 2015), the general notion that progress is achieved by overcoming the restraints of nature prevailed (Chakrabarty, 2018). Hence, *Aniara* is dystopic since it envisions the loss of not only an open horizon of expectation but also a relatable past. When the *Aniara's* flight from the ruined Earth fails, past deeds catch up with the lost refugees, but everything is already lost to infinity.

This chapter aims to discuss history curricula as an educational project in the Anthropocene epoch. Due to human influence, widespread and rapid changes have affected the atmosphere, ocean, cryosphere, and biosphere, fundamentally reshaping the conditions for life on Earth (Arias et al., 2021). These events are not dystopic fiction but, rather, they are the actual events that have situated us in an unprecedented predicament. As the effects of crossing planetary boundaries are irreversible, this seems to negate the notion of an open future—which, for Koselleck (2004), constitutes the core of modernity. However, it also seems to negate history as a relevant source of orientation, as narratives that separate human experiences from their environment (nature, climate, animals), is becoming obsolete. The present challenge is to find workable steering mechanisms to mitigate global warming and avoid a sixth mass species extinction. However, while investment in new technologies is necessary, it is not enough. According to The Intergovernmental Panel on Climate Change (IPCC), major lifestyle changes in how we live, travel, and consume are also required (Arneeth et al., 2019). Perhaps paradoxically, the mere thought of entering a new type of normality seems to trigger societal uses of history. The search for a new historical self-understanding is basically about ideals of *Bildung* or formation and should be of concern to anyone who takes an interest in the contemporary relevance of history education.

In outlining the scope of this chapter in greater detail, I must also remark on what not to expect. Combining education and history with the Anthropocene seems to raise expectations that might not be fulfilled. First, this *educational approach* does not

concern how best to teach or learn about climate change or sustainability. Rather, the task concerns the intended curriculum and strategies for incorporating new perspectives into the whole of historical learning. Second, *history teaching* in this context does not refer to specific environmental inquiries but to the impossible yet necessary task of teaching the bigger picture. As Shemilt (2000) observes, “The logic and methodological apparatus of historical enquiry can be applied to fragments and episodes in the past, but not to the past as a whole” (p. 85). The debate on climate change reveals that all claims are not equally valid and that, therefore, how the past is interpreted matters (Dunlap and McCright, 2015; Hunt, 2018). Drawing on the philosophy of history (Rüsen, 2017), humans’ historical consciousness affects how we orient in the world—that is, we cannot help but interpret the past in relation to what we expect from the future while we make sense of what is going on. Now, the Anthropocene is an unprecedented predicament that has caught curriculum-makers (including teachers) in a new situation where they might need to rethink what is relevant for study and what becomes significant when explaining historical processes, as well as who and what should be included or excluded as historical actors (Bladh, 2020; Nordgren, 2021; Van Straaten et al., 2016).

Third, taking the *Anthropocene* concept into the field of history causes epistemic confusion—not only because it is a geological epoch (which is still under investigation)—but also because it comes with a perspective that, by and large, has been a blind spot for the humanities’ generally anthropocentric self-understanding (Chakrabarty, 2009; Simon, 2019). The pacing and naming of geological epoch shifts are seldom of public concern. This shift does not take place in early evolution, or as slow-moving interglacial periods—nor does it originate in an alien meteorite collision, like the one that ended dinosaurs’ rule; rather, it results from recent human activity. The very term *Anthropocene* implies a matter of concern beyond the stratigraphic societies, that decides on geological successions. This shift is not traced from the slow-moving evolution of plankton—nor does it originate in an alien meteorite collision, like the crisis that ended dinosaurs’ rule; rather, it results from human activity (Crutzen, 2002). The *Anthropocene* is not an uncontested concept since many scholars have rejected a definition that starts with a generalized *Anthropos/humanity* and argued for a name that more specifically attributes blame. Among the alternative suggestions are the *Capitalocene*, pinpointing capitalism (Moore, 2017), and the *Plantationocene*, tracing the crisis’s causes to colonial agriculture (Haraway, 2015). This chapter will not engage much with this debate but will accept the *Anthropocene* as a historical periodization. The concept may be useful since it can be open to simultaneous perspectives: it can encapsulate a range of endangered planetary systems (not just climate change). Geologically, it does define a specific cause and time for transition—but without reducing the matter’s complexity to teleological closures in specific historical processes (Thomas, 2019). Moreover, it does indicate generalized human capabilities—but without denying that actions are linked to specific actors and regimes of powers. It situates humans at the center of the narrative, but it does so from a planetary perspective that decenters humans as entangled in—and dependent on—larger ecological systems. Naming an epoch is a discursive and homogenizing project, but not to the extent that the label will restrict what can be storied. As a product of periodization, the *Anthropocene* does not provide answers; rather, it offers an outlook from which to raise questions.

From here, we can reconnect to the curricular perspective with the help of Latour (2014), who formulated the simple but precise question: “How do we tell such a story?” (p. 3). He poses this question about the *Anthropocene* to the academic field of knowledge production, displaying the insecurity surrounding the consequences of producing new knowledge. This chapter suggests that Latour’s question is equally relevant to the field of educational recontextualization. History education research, so far, has produced surprisingly little on this matter (McGregor et al., 2021; Metzger and Harris, 2018). Historicity is intimately associated with the formation of modernity (Hunt, 2014), and curricular attempts to answer Latour’s question will eventually test whether history, as a specialized gaze, can also provide powerful knowledge for orientation in the age of the *Anthropocene*. To paraphrase Young (2003, p. 102): if, as curriculum theorists, we cannot tell what is important to know in the age of the *Anthropocene*, the epoch’s story will likely not be told, or it will be filtered by administrators and politicians’ pragmatic and ideological decisions.

The curricular challenge and the reciprocal device

Chakrabarty (2009) has proposed that the distinctions between *natural* and *cultural* history might collapse, arguing that from now on, planetary conditions are what will give history meaning. In 1916, when Dewey (1980) reflected upon history and geography as school subjects, he ascribed both of them with particular features, but rightly studied—that is, according to Dewey, jointly—they could offer students a holistic method with which to master the world. As complementary resources, they would reveal how human civilization is associated with its natural surroundings:

While geography emphasizes the physical side and history the social, these are only emphases in a common topic, namely, the associated life of men. For this associated life, with its experiments, its ways and means, its achievements and failures, does not go on in the sky nor yet in a vacuum. It takes place on the earth. This setting of nature does not bear to social activities the relation that the scenery of a theatrical performance bears to a dramatic representation; it enters into the very make-up of the social happenings that form history. Nature is the medium of social occurrences. It furnishes original stimuli; it supplies obstacles and resources. Civilization is the progressive mastery of its varied energies (p. 247).

Dewey’s argument for combining nature and history was not to critique modernity or Western civilization. For Dewey, the learning object was the trajectory of humans’ progressive mastery, for which nature was an obstacle or a resource. Still, he noticed that nature was lacking as a dimension in the historical explanation of culture. Today, policy-makers and curriculum-makers are

again more inclined to promote holistic or cross-disciplinary approaches, arguing that subject boundaries are obsolete or hindering change (e.g., Gough, 2021; Wals and Corcoran, 2006). However, this assumption that disciplines fragmentize a coherent whole obscures that knowledge beyond common sense derives from specialized ways of exploring the world (Deng, 2020; Young and Muller, 2016). Undoubtedly, an understanding of the Anthropocene presupposes interdisciplinary collaboration, in both science and education. Such collaboration presupposes, rather than replaces, epistemic boundaries (Nordgren, 2021). However, if history as subject-specific education fails to respond and does not provide useful tools with which to explore global challenges, it will solidify into dogma.

Education requires ideas about what it is to know something and how this knowledge relates to students' existing understandings. It requires the means to structure this content, making it accessible and conceivable for students at each stage of their progression. Young and Muller (2016) stress that education's fundamental task is to offer tools with which to explore the world and think beyond immediate circumstances. These tools are not randomly collected but rooted in specialized knowledge, which in turn is dependent on disciplinary communities. However, as Deng (2020) notes, education is also a normative project of *Bildung* or formation that involves students in the process of becoming a person among other persons and a member of specific communities. Making history education relevant in a changing world requires both a rooted idea of its specialized gaze and a notion of the times' apparent epochal challenges (Klafki, 1995).

The first questions about learning history are: Why bother? Why study history when previous experiences seem to expire so quickly? What can history possibly offer more than nostalgia when human activity had brought us to an unprecedented situation? One possible answer is that crises tend to trigger the human impulse to historicize predicaments. While climate change calls for immediate action, the willingness to change arguably requires a renewed historical self-understanding. Another possible answer is that crises are temporary, but learning to live with their consequences is a long-term engagement. This is a reason to reflect upon the direction of educational formation or *Bildung* in this new epoch. The human capacity for history seems inherent to our neurological disposition to remember and reflect, as well as our social urge to communicate through symbols. As Woolf (2019) points out in his book on global historiography, the human capacity to remember and communicate makes historical cultures inescapable. At the heart of any culture, one can discern the communication of collective memories—and how some of these discourses tend to dominate others since they have been selected and institutionalized in narratives, traditions, symbols, calendars, education, et cetera (Assmann, 1995; Rüsen, 2007). In his bestselling book *Sapiens: A brief history of humankind*, Harari (2014) collects examples of how politics, faith, law, and currency that signify complex societies are fundamentally based on expansive narratives. Again, how and by whom the Anthropocene is storied matters.

Obviously, disciplines and school subjects are inherently historical constructions and, thus, changeable. From this changeability, it does not follow that all knowledge claims are equally arbitrary or fortuitous. Everyday knowledge is situationally grounded, and it differs from specialized knowledge, which emanates from methodologies, categories, and epistemic communities that evaluate their findings. This logic of specialization creates borders that determine what is accepted as valid and relevant knowledge and what is not. Hence, disciplinary borders both hinder and drive advancement and communication. Their language can exclude, since access requires a special inauguration (Foucault, 2020), yet it is also inclusive since its concepts and methods allow for precision and transparency (Young and Muller, 2016). Specialized knowledge regimes develop a grammar that provides learners with tools to think beyond a given context, which Young and Muller (2016) call *powerful knowledge*. Thus, history, when disciplinarily framed, risks excluding relevant information (e.g., from geography) while also including an apparatus to produce knowledge that other perspectives cannot.

Keeping history teaching meaningful in a changing world requires a constant hermeneutical process that opens the school subject to a reciprocal exchange between what is to be explained and what that explanation requires (Fig. 1). That is: What is considered significant to explain, and what epistemic considerations does that explanation require? The discipline or subject explores the world through the tools of its grammar of specialization. This grammar can effectively enable a better understanding of the Anthropocene as a complex yet comprehensible phenomenon by providing perspectives on, for example, continuity and change in humans' relationships with nature. However, a problem arises in that the subject's epistemic traditions tend to disregard environmental relationships as being historically significant, and consequently, the disciplinary grammar might not be adjusted or fully equipped (Chakrabarty, 2009; Simon, 2019). Since the Anthropocene is a geological conceptualization and a predicament with

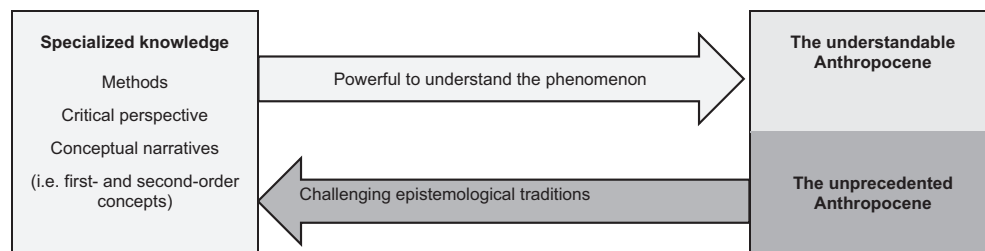

Fig. 1 A reciprocal device to consider the Anthropocene The epistemology of school history is based on a grammar of specialized knowledge. This grammar can be powerful when exploring and understanding the Anthropocene. However, the ambition to explore the historical dimensions of the Anthropocene will challenge epistemological traditions within the subject.

historical, political, social, and ethical consequences, its complexity challenges the borders of historical knowledge. Hence, the Anthropocene is not just another phenomenon to be explored and learned; rather, it requires explanations that make the historical landscape look different.

Nonetheless, the Anthropocene is not mysterious. Historians cannot hope to give a holistic explanation of it but, rather, to offer a relevant grammar of specialized knowledge with which to explore and add historical dimensions. Translating the Anthropocene into new narratives will conflict with and transform dominant ideas about historical significance, and previously marginalized events—such as climate change, volcanic eruptions, and the relocation of microbes, plants, and animals—will become more central. Such a shift in curriculum might open a floodgate to additional events and perspectives, which returns to the question of how to tell this story.

Storylines for the Anthropocene

When people reflect on their own time, they tend to sense an unprecedented period of transformative upheaval. Occasionally, the adjective *unprecedented* proves accurate. The Earth is now leaving behind the relatively stable climate of the Holocene period, which started after the most recent glaciation, about 12,000 years ago. Currently, the International Commission on Stratigraphy (ICS) is tracing the origins of this transition. The core of geological time division is the dramatic evolutions of life on Earth from its emergence, photosynthesis, and the Cambrian surge of complex life forms (Lewis and Maslin, 2018). Periodization is set on an official scale, based on methods and procedures for adding and changing time deviations. This system derives from the physical observation that any given stratum of rocks is older than the strata above it and younger than the strata below it. By comparing rocks and fossils throughout the world, geologists have divided and subdivided the Earth's 4.5-billion-year history into eons, eras, periods, epochs, and ages. These shifts mainly correspond to fossilized organisms' origins or extinction—which are, thus, traceable in sediment. The resultant stratigraphic question is: What physical reference point in the strata can define the beginning of this new epoch?

The candidates for such a *golden spike* are: the Neolithic revolution, with its consequences of domesticating plants and animals; the initiation of globalization through the Columbian Exchange in 1610; James Watt's improvement of the steam engine in 1788, which sped up the Industrial Revolution with the use of fossil fuel; the plastic revolution, which started in the 1920s; and the nuclear fallout after the Trinity test on July 16, 1945. In one sense, the Anthropocene does not differ from other geological types of periodization. Whether it will be accepted as an epoch depends on what can be scientifically established from sediment. In another sense, this periodization is novel. An unusual consequence of a geological label is that it inevitably signals that humanity's past and future choices will affect the future conditions for life on Earth. Since measures can be taken to reduce these effects, they are highly controversial. Lewis and Maslin (2018, p. 73) remark, "Geology plus humans equals politics." In fact, the concept's impact has already begun—regardless of any ICS decision, the Anthropocene has escaped seminar rooms and laboratories. Hence, as geological periodization has entered the realms of historical time, and the quest for a golden spike has centered sediments in contemporary political attention, it has also started to reshape the historical understanding of human cultures as not solely a human affair.

This scientific, conceptual, and political intricacy sets the scene for curriculum development as a reciprocal device. The geological concept brings new dimensions to historical thinking that can practically orient the discipline to discover climate, weather, natural forces, biodiversity, and environmental entanglement as fundamental dimensions in historical processes (Chakrabarty, 2018; Robin, 2013). However, geological timescales are based on different logics and methods and are not easily incorporated by historians' less paradigmatic and more contextual uses of periodization. Historical inquiries do not start or stop with golden spikes in rock strata and ice cores. A new periodization will trigger historians to trace origins and patterns from previous times.

Incorporating the Anthropocene into the historical gaze will rupture both established analytical models of inquiry and historical syntheses and overviews. For instance, notions of historical significance seem to be pushed in at least three different directions—all of which are slightly outside the comfort zone of history teaching. First, to perceive how natural and climatic continuity and change interweave with human cultures, a *longue durée* (long duration) of geological changes and early human history has been advanced. This perspective implies a timescale more familiar to archaeologists and geologists than historians (Ljungqvist et al., 2021; Robin and Steffen, 2007). Second, to grasp the Anthropocene's direct causes and effects, the field of study is compressed into the highly politicized timeframe of contemporary history (McNeill and Engelke, 2016). The third direction concerns historical consciousness; as the present reshapes the past, it also reshapes expectations for the future (Chakrabarty, 2018).

The long duration

To historicize nature, and to put climate change and the loss of biodiversity into perspective, a long storyline with a broad outlook from natural history or "Big History" is needed. Several periods of cold, drought, humidity, and storms have, arguably, influenced the whole of human history—from the exodus out of Africa to the droughts that doomed Akkad and Mayan culture, the Medieval warmth, and the cold period that preceded the French Revolution (Headrick, 2020). Climate change affects geographical areas differently since the respective underlying connections are complex, and because the current circumstances are unprecedented, these effects are difficult to predict. For example, from 7000 to 3000 BCE, the average temperature in the northern hemisphere was about 2–3 °C (Celsius) higher than the current average. Based on big data analysis, Zhang et al. (2011) show that cold periods correlated

with population dips from the 800s to the 1800s CE. War, conflicts, and migration are often closely related to climate change. Hence, fluctuations in temperature are not unprecedented, nor is species' extinction. What is unprecedented about the Anthropocene period is the causes, pace, and situation, with a human population exceeding 7 billion. The current rapid warming cannot be explained by the Earth's systems or solar activity (Arneth et al., 2019; Pachauri et al., 2014). To grasp these trends, points of reference are needed that only deep history can provide.

The short story

To understand the seriousness of the Anthropocene's not "just" being about how any human society has affected its surrounding ecosystem, humans' current effects on the planetary system must be understood. Whether its starting point is set at the Columbian Exchange or from James Watt's improved steam engine, history picked up speed after WWII. Since 1945, during a timespan no longer than it takes for a person to grow up and grow old, the world population has nearly tripled, while the animal wildlife population has decreased by more than half. This trend points toward a sixth mass extinction, including 75% of species going extinct in the next few centuries (Ceballos et al., 2015). The annual production of plastic has risen from 1 million tons to about 380 million tons, and microplastic particles are now virtually ubiquitous in our waterways and oceans. Nitrogen-synthesized fertilizer production increased from 4 million tons to more than 85 million tons, while chemical cycles are turning seas and rivers into dead zones. The number of cars has increased from 40 million to 850 million, and carbon dioxide has increased exponentially (McNeill and Engelke, 2016). Climate change is causing glaciers to melt, sea levels to rise, and severe weather events—such as floods, droughts, and hurricanes.

The short story of the Anthropocene is a controversial tale of the uneven consumption and destruction of natural resources. It is about economic globalization and the spread of wealth and education. The distribution of responsibility matters. Africa accounts for less than 3% of global emissions of greenhouse gases, but it experiences water stress due to climate change that could threaten the well-being of up to 600 million people (Malm and Hornborg, 2014). Extreme poverty has decreased over the last 40 years, but this trend is now reversing, partly due to the climate crisis (Arneth et al., 2019; Pachauri et al., 2014). The accumulation of wealth and the reduction of poverty have, so far, come with higher energy consumption. A burning question is how to get millions of people out of energy poverty without significantly increasing greenhouse gas emissions (González-Eguino, 2015). To reduce humans' impact on the Earth's systems, global and local solutions must be developed to even out injustices and eradicate poverty. Historical knowledge might offer powerful perspectives when exploring such a wicked problem and a perspective from which to discuss climate justice (Incropera, 2016).

A new historical culture

While awareness of the endangered planetary system is slowly sinking into our political and historical consciousness, the conclusion seems paradoxical: humans have become a force of nature and, thus, more powerful than ever—but this power has redefined nature from an infinite well of resources to a complex system of interconnected processes that are endangered. The growing insights that previous actions have mortgaged the future demand new narratives about historical origins, possible effects, and options (Chakrabarty, 2018, 2009). This perspective suggests a need for new historical orientations. One aspect of these necessary changes is the physical threat to memory culture, anthropology, and archeology. Rising sea levels are consuming coastal sites, and acidification and variations in precipitation are eroding buildings and statues (Fatoric and Seekamp, 2017). Climate change and deforestation are destroying ways of life for Indigenous peoples around the world (Chakravarty et al., 2012). Furthermore, rising soil temperatures are degrading the quality of archaeological evidence (Brunswig, 2014). Hence, traces of the past are literally eroding. Another aspect is the cultural consequences that can derive from both cognitive and emotional detachments from how we have learned to make sense of the past and future. Possibilities for change appear less as opportunities and more as necessities. Although cultural trends are unpredictable, threats also trigger investments in future technology, artificial intelligence, and genetic engineering, and crises might nurture new utopian visions.

Contradictory but connected trends seem to frame a new emerging historical culture. Thus, in Latour's (2014) question, the problem that must be storied is not simply about responding to the present situation or learning about the causes and consequences of the Great Acceleration. The question is an intellectual challenge to contemporary historicity, as well as critical theory and post-humanism. The obvious collapse might be the separation of culture and nature. Still, re-storying history must also find ways to encompass humans as both exceptional and non-exceptional, exploring both universal and particular causes and consequences. As Rüsen (2012) reminds us, the sweeping and widespread criticism of modernity and enlightenment is rather one-sided. While the division between nature and culture has been dominant, ideas of ecocriticism and other alternative narratives have always been parts of these multilayered traditions (Hinchman and Hinchman, 2001). Today, the fast-growing youth movement Fridays for Future combines an ecocentric vision and demands for climate justice with a rather technocratic reference to science and scientists (Zulianello and Ceccobelli, 2020).

Taking on the Anthropocene in history teaching is also about finding pragmatic strategies to tell this story. Possibly, the stories that come to be told are what shape the historical culture.

Curricular strategies

History as a school subject must be relatable to a range of curriculum goals (Chapman, 2021). Therefore, developing a history curriculum in the time of the Anthropocene raises a spectrum of questions: Does history have a specialized knowledge that can offer relevant perspectives on what it is to live and act in this new age? Can history provide useful answers about what brought us to this juncture? Can history offer relevant scenarios as inputs on what should be done from here? Answering such questions gives rise to new considerations; for instance, the postcolonial and Marxist critique of construing the human species as a unified historical actor evokes questions about agency and power structures since the consumption of the Earth's resources is not equally distributed (Malm and Hornborg, 2014; McEwan, 2021). In the field of posthumanism, the humanities' preoccupation with human culture is critiqued for decentering the larger ecosystem (Tyler, 2021; Wolfe, 2010), evoking questions of how to historize interrelations with non-humans. Eco-critical perspectives often direct their critique toward disciplinary borders and "the ranking of knowledge systems that places Western science at the top of an epistemological ladder" (Rose and Robin, 2004), which also evokes questions about different epistemic worldviews (Graeber and Wengrow, 2021).

Latour's (2014) question of how to story the Anthropocene is, indeed, an entry point into this challenge facing teachers and curriculum-developers. Teaching is practical, which shifts Latour's questions from rhetoric to practice: How do we, as teachers, recontextualize the long duration with the shorter story and in relation to the conflicting influences of a historical culture in crisis? A useful curriculum requires decisions and selections. One inspiration can be Seixas (2000), who has framed three possible teaching strategies to approach contested or controversial historical content. Using an example from Canadian colonialism, he discusses how teachers can address such historical problems. These strategies are outlined as generic epistemological positions, and as such, they offer a relevant starting point from which to reflect on integrating the Anthropocene into history curricula.

Seixas calls the first strategy "enhancing collective memory," which seeks to provide students with the one most accurate story, based on current knowledge. If different interpretations are available, one interpretation likely has more credibility. This is the best story and the one that should be taught. This strategy's advantages are that it gives teachers a cohesive storyline to tell and students an authorized point of view. Shared narrative creates a common experience and, perhaps, even a sense of a moral trajectory. The second strategy is to engage students in exploring the past, and drawing their own conclusions based on evidence. Rather than receiving a digested narrative, students learn to be critical but also to understand the limits of interpretation. This strategy is both educative and democratic, and as such, it fits well with an approach that Seixas calls "disciplinary." The third strategy accepts different opinions and focuses on the causes of the historical controversy, asking: Who are the advocates, and what are their interests? Seixas categorized this strategy as a "postmodern strategy" since it is not concerned with what happened in the past but, rather, how the past is narrated and used by different interest groups. This approach also invites students into inquiries—not about the past but about the use of historical narratives in contemporary culture.

Seixas is, to some extent, open to drawing from all three strategies. However, he advocates for the second, the disciplinary strategy. Seixas critiques the best story strategy since it cannot adequately present the complexity of a historical problem. Instead of enhancing critical historical thinking, it supplies a one-sided and, therefore, seductive collective memory. The postmodern strategy offers the advantage of drawing attention to narratives' seduction and pervasiveness. However, it does not engage with the past or actual conflict—only with its aftermath. Seixas warns that this approach can lead students to relativistic assumptions.

Including climate change, the environment, and biodiversity into curricula seems to thwart any ambition to tell one "best story." The Anthropocene adds more events, accents, motives, and inquiries to an already crowded agenda; new perspectives on time, agency, and causes seem antithetical to a cohesive collective memory. The postmodern strategy seems to be more useful in deconstructing anthropocentric narratives. However, per Seixas's argument, the postmodern approach would still fail to understand how the Anthropocene is based on real events. The disciplinary strategy would engage students in exploring the Anthropocene as a range of historical problems. As Gibson (2021) has noted, historical thinking concepts are well suited to helping teachers' inquiries of the Anthropocene and its significance, beginnings, causes, consequences, and ethical considerations. For instance, was the French Revolution caused by bad weather (Fagan, 2000), and did British industrialization bring the American bison to the brink of extinction (Taylor, 2011)? Hence, the "best narratives" strategy seems the most obviously dismissible. One aspect on which both the disciplinary and postmodern strategies agree is implementing multi-perspective curricula.

However, the choice of teaching strategy might not be so straightforward. Neither the disciplinary nor the postmodern strategy actually provides a basis for selection; everything that can be inquired about is a potential interest, and the means of deconstruction do not provide clues about what to construct. Nonetheless, teaching requires criteria (implicit or explicit) to select what is significant enough to be taught. Hence, the demarcation lines that separate the disciplinary from the postmodern, and the best-story approaches seem too definite, tending to obscure how all 'inquiries, deconstructions and collective memories' are embedded in the meaning-making processes that precede them. The curricular problem is not whether inquiries about the Anthropocene are teachable; rather, the problem is how to establish conventions in which the Anthropocene, as an epoch and a perspective, become inevitable and integrated parts of course activities. Consider a parallel with intercultural education: while nationalistic narratives play a less predominant role in many national curricula, educational metanarratives are still structured by narrative scripts that center nations and decenter migration and cultural encounters as core topics of exploration (see Carretero et al., 2012; Nordgren, 2017). Following this logic, the crux of renewing the curriculum is to find strategies that integrate the Anthropocene as a historically significant problem.

Historical significance is a prominent theme in the educational research literature. The process of selecting content is neither random nor arbitrary. Notions of what is significant can be linked to events of special importance, profundity, quantity, and durability (Lévesque, 2008). However, as Seixas (1997, p. 22) underlines, this process of selection does not emanate from the past itself but, rather, from the “interpretative frames and values of those who study it—ourselves.” Thus, we curriculum-developers engage with a past filtered through mental frameworks shaped by personal and educational experiences (Lévesque, 2008). Empirical studies on significance have often relied on questionnaires and interviews that collect what students, teachers, or textbooks identify as most important. According to Barton (2005), such methods are “well-suited to this field of inquiry because issues of significance are inherently about ranking—they involve deciding which topics are more important than others” (p. 12).

However, efforts to integrate the Anthropocene (and intercultural learning) into teaching reveal that significance is a gatekeeper that goes beyond individual interpretative frames and curriculum-developers’ personal and educational experiences. To analyze its logic requires, more than a ranking list, a critical methodology with which to read between the lines in order to transcend individual preferences and observe general patterns. When we make these connections, the content and inquiry tasks that structure our courses can reveal the structure of a master narrative; when we consider the range of events and processes that we find hard to integrate not just as missing parts, but as anomalies, we expose the paradigmatic framing of the historical regime (Hunt, 2014). Seixas’s repertoire of teaching strategies operates within the same overarching master narrative. The three identified strategies are helpful in discussing epistemic stances but insufficient as means to rethink what should be framed as historically significant. Hence, we must ask whether the Anthropocene indicates a new master narrative in history teaching.

Master narratives’ rule and role

Historians and history educators are generally skeptical about narratives with transcendent or universal ambitions—and for good reason. History has frequently been used by states and political groups to legitimize ideologies and homogenize worldviews, whether nationalistic, Marxist, or liberal. Agreeing with Sirkka Ahonen (2017) is easy when she dismisses such master narratives as “unsustainable as truths and socially exclusive as identity builders” (p. 58). Samuel Wineburg (2013) warns that critiques of Western-biased curricula should not try to replace one master narrative with another. For Evans (2011), history educators are obligated to debunk the myths of master narratives in order to promote multi-perspectivity. Hence, the ideal history curriculum seems to be free from master narratives, but is a curriculum with purely neutral ordering principles possible? Can historical synthesis be learned without overarching meaning transcending from the sum of many multi-perspective voices (cf. Ankersmit, 2001)?

The scholarly literature tends to present the notion of master narratives with rather persuasive definitions, attaching specific value-laden attributes to the concept. Such specific contextualization is often suggested as constitutive features. According to Moyers (1990), a master narrative is an ideological script imposed by an authority on everyone else. For Woodson (2017), it is a dominant mythology that mutes, erases, and neutralizes the features of racial struggle. According to Carretero and Bermudez (2012), it is a simplification and exclusion that are essential for nations and nationals. When Carretero and Van Alphen (2014) empirically examined how master narratives affect students’ learning, they defined the concept as the opposite of disciplinary thinking.

However, rethinking a curriculum seems to require a further contemplation of how narratives structure historical consciousness. First, I suggest that we avoid equating the organization of the story with the actual plot that gives it a specific meaning (see White, 2014). Nationalistic history persists not only because of its ideological content but also the efficacy that a nation, as an overarching idea, can be used to organize the historical who, what, where, and when. A master narrative is not the same as the myth that it is narrating but, rather, the logic by which it assembles different narrative elements into a shared meaning. For example, an account becomes a master narrative not by reproducing stories about national greatness but by presenting the nation as the obvious protagonist. As Halverson et al. (2011) suggest, (master) narratives are not just stories centered on specific and situated events but, rather, systems of stories that form culturally recognizable trajectories of overcoming conflicts. Likewise, I suggest that we avoid associating master narratives with only some cultures, that nation-states produce homogenizing narratives while advocates for cosmopolitanism do not, that Western modernity makes universalistic claims while postmodern and postcolonial claims are only local, and that only authoritarian regimes suppress alternative narratives while liberal democracies are open to multi-perspectives. The argument against such an oversimplified association seeks not to deny differences between historical, ideological, and epistemological positions but to acknowledge that the distance between them occurs as tensions, not dichotomies (cf. Mignolo, 2002). Klein (1995) presents an interesting example of culturally transcendent meanings’ critical persistence: Lyotard criticized historical narratives for reducing enslaved people’s local suffering to grand stories, while Clifford Geertz feared that Lyotard’s construct would reduce enslaved people to a locally unified suffering object. The paradox of writing history in a postmodern culture is well expressed by Klein (1995, p. 298): “We are living a golden age of global narratives in which universal history is not simply possible, but unavoidable.”

In anthropology and narrative psychology, stories are often viewed as constitutive for people’s identity formation (Bruner, 1990; Polkinghorne, 1988). Humans have the cognitive disposition—or burden, according to Nietzsche (2008)—needed to connect past experiences and utterances into coherent narratives that give or even impose meaning. Since stories are shared through language and communicative exchanges, they are what Geertz (2008) describes as the fabric that creates culture. This role implies that we live in a web of narrative significance spun from countless stories. To distinguish functions and systems within this narrative network, McLean and Syed (2015) suggest a threefold distinction: *master narratives*, *personal narratives*, and *alternative narratives*. A master narrative is not a specific story but, rather, dominant scripts that contain collective storylines, ranging from a group’s history to

notions of what inhabiting a particular social category means. These scripts can be identified in cultural products and discourses—for example, in curricula and textbooks (Hammack, 2010). Personal and alternative narratives are influenced by, but not reducible to, these dominant storylines. Tensions and contradictions occur between different scripts, and as McLean and Syed (2015) emphasize, master narratives are always present alongside narratives that will counter them:

As individuals construct a personal narrative they negotiate with and internalize these master narratives—they are the material they have to work with to understand how to live a good life. For many individuals whose lives fit in with societal structures, these master narratives are functional and unproblematic. Others, however, may need to construct or adopt an alternative narrative, which at minimum differs from, and at maximum resists, a master narrative (p. 320).

This sectioning of master, personal, and alternative narratives can help curriculum-makers explore the Anthropocene's integration into history education by identifying interrelated narrative structures that transcend the teaching structures Seixas discusses. Master and alternative narratives are not imposed as "the best story" but as storylines that strongly influence their audiences' orientation toward what seems central or peripheral, historically significant, and socially valuable. For example, these storylines can support ontologies, such as the hand of God, the invisible hand of the market, or history's expression in class struggle. They can collect diverse but influential ideological, scientific, and esthetic traditions—such as the Enlightenment or postmodernity—and they frame emerging narratives, such as the Capitalocene or the Anthropocene.

However, the relationship between alternative and master narratives is complex. McLean and Syed (2015) characterize this relationship as ironic: the challenge that the alternatives pose might influence and even change the master narrative. Most often, the alternative narrative paradoxically reinforces what it opposes since the act of expressing alternatives gives dominant scripts recognition and opportunities to adapt. For example, migration studies have—despite researchers' intentions—been used to mirror nationalist images of normality (Wimmer and Schiller, 2003), and endeavors to strengthen teaching in the United States about the civil rights movement might paradoxically reinforce notions that "the race-problem" is in the past and has been overcome (Woodson, 2017). When Seixas (2000) introduced his three alternative strategies, he referred to a specific event concerning a treaty between the Nisga'a people and the government of British Columbia, Canada. Now, this story describes a (real) event that makes sense in any contemporary history class. The topic might be provocative to a nationalistic agenda, but in a multicultural society, such cases are to be expected. As such, it is an alternative narrative that does not undermine the dominant scripts of methodological nationalism, just as single inquiries on climate change will not rupture the anthropocentric embeddedness of history.

The basic assumption is that master narratives cannot be escaped. Some ordering scripts, patterns of interpretation, understandings of significance, and values will dominate over others; however, they will never do so with total hegemony. If an alternative discourse becomes influential, it might structure a new master narrative. When exploring the possibilities for a history curriculum in the Anthropocene, slightly modifying McLean and Syed's (2015) model by adding one more position could be useful; as discussed by Somers (1992), cultural and institutional formations larger than individuals are also part of this game. Collectives, networks, and institutions are both recipients and producers of narratives. Academic disciplines and curriculum-makers produce conceptual narratives that interact with—but are not reducible to—sociocultural or national master narratives. Further, digital media have become accessible to a diverse range of interest groups who have added numerous public narratives that can both undermine and support master narratives (Levinger, 2018).

This modified model (Fig. 2) might help discern relevant positions in the curricular context when introducing the Anthropocene to history teaching. Since national and regional curricula reproduce master narratives to which ecological perspectives, migrations, and cultural encounters are anomalous, they seldom surface in history classrooms.

However, such alternative narratives can rupture stability because they are produced by public actors who can influence the historical culture. Curriculum-makers (such as disciplines and other epistemic communities) can, from their institutionalized positions, revise paradigmatic discourses. These conceptualized alternatives form the narratives that social movements use to pressure the political and economic systems. Networks with other interests can also use social media to produce public narratives that undermine or discredit scientific knowledge. Hence, when we curriculum-makers regard education and disciplines as part of public narratives, we can discern how they can simultaneously be fundamental to both the dominant master narrative and critical alternatives. Adolescents form personal narratives in the turmoil of competing narratives. If history education cannot constructively contribute to students' ability to inquire and deconstruct different narratives, and also to grasp a bigger picture, the subject might become irrelevant. The growing discrepancy between experiences of an endangered planet and a historical curriculum detached from these experiences might eventually marginalize history as powerful knowledge.

Telling the best story according to evidence might lay a good foundation for understanding the big picture of how humans spread across the world and fundamentally changed the face of the Earth—first locally, then globally, and now on a planetary level. Meanwhile, a disciplinary approach might inquire about the reasons behind events, such as the Lisbon earthquake of 1755, or the Lyton Creek wildfire in Canada in 2021. Conversely, the postmodern strategy can usefully deconstruct the oil and gas industries' lobbying compared to how the tobacco industry tried to dismiss the harms of smoking. However, none of these strategies have a grammar with which to re-evaluate what to study. Therefore, some isolated environmental events will be tolerated and thought to fit within the current master narrative. Then again, alternative narratives without ordering principles will not be embedded into

Fig. 2 The modified master narrative model. McLean and Syed's (2015) master narrative model describes personal narratives as derived from a balance between master narratives and alternative narratives. Drawing on Somers (1992), a relation to the public narrative is added. Public narratives are attached to cultural and institutional formations larger than the single individual. The bidirectional arrows indicate that individuals and public groups (e.g., disciplines and curriculum-makers), through their narratives, both internalize and create or sustain master narratives (arrows 1 & 4) and alternatives (arrows 2 & 5), and that alternative narratives are related to one another (arrow 3).

the synthesized line of development that lays the foundation for content selection and explanatory perspectives. These shortcomings of the three teaching strategies again raise the question of whether the Anthropocene indicates a need for a new master narrative in history teaching.

Possible alternatives

Sometimes, art and fiction dispense heuristic insights with which to explore how anticipating the future affects historical understanding. The condensed narrative of Harry Martinson's doomsday poem encompasses both the diversity among the passengers and their shared fate inside the *Aniara*. The spaceship, lost without steering capability, might also indicate another and an even more disturbing reflection: despite all scientific evidence revealing the need for immediate action, national and global authorities and enterprises are still reluctant to act. We who live in the part of the world that consumes most of its resources still have not incorporated this evidence into the narratives by which we orient our lives.

Historical knowledge is horizontally structured, allowing different and even competing theoretical and ontological outlooks within its disciplinary gaze. Nevertheless, historical consciousness seems to be affected by deep narrative patterns with paradigmatic qualities. These patterns form a web of coherence and significance that could be termed a *genetic historical regime*. School history can sometimes appear as one damned thing after another, but this appearance is an illusion. Selecting and pacing events to study is not a random process. It follows an established trajectory that tends to overstate geopolitical entities and marginalize migration, cultural encounters, nature, and climate as historical factors. In 1958, Braudel (1972) advocated for a long-term geographical perspective as a way to illuminate the environmental effect on human social and economic life, as well as on human mentality. History, he argued, is also the "long centuries of climates, of vegetations, of animal populations, of types of crop, of slowly constructed equilibria" whose elements cannot be transformed "without the risk of endangering everything" (p. 172). Today, we know the equilibria are raptured and that everything is endangered, but we have not found the key to writing this story.

Reforming the history curriculum must be about what signifies a sound historical culture in the Anthropocene. Certainly, we cannot just request or order a new and ready-made master narrative and, as curricula are ultimately politically framed, we should be very careful what we wish for. Based on specialized knowledge, the climate threat and human activities' impacts on the Earth's future have been detected. Teachers and educators must take responsibility as curriculum-developers and use a range of educational strategies to develop relevant and concrete inquiries, deconstructions, and individual expert narratives—but we must also dare to explore forms and principles for new synthesizing perspectives.

Several world-history projects have explored alternative narrative structures, including McNeill and McNeill's (2003) exploration of globalized networks. Frankopan (2015) has used the Silk Road as a way to unravel global development, and Big History is a multidisciplinary project to read history through big data (Christian, 2011; Bain, 2019; Galdi and Armitage, 2014). However, the environmental history field is, according to Hornborg (2010), reluctant to theoretically relate environmental change to political, economic, and cultural power structures. In teaching history, the future is most often a silent but salient point of reference. It often looms at the end of textbooks as fragmentized reports of contemporary threats and conflicts. Without a reciprocal device, the Anthropocene predicament will be added as events in the final chapters of the textbooks', while the subject outdates itself. By challenging and exploring narrative structures, we might develop ways to synthesize historical outlooks. This exploration might lie beyond the comfort zone of multiperspectivity, but it is not an ambition to tell a singular story.

If master narratives are understood not as hegemonic narratives but as scripts that help and, thus, also direct our ability to create coherence and meaning, we realize that the question is incorrectly formulated. The question is not *if* but *which*. Shemilt (2000) wrote about the need for a polythetic framework that can paint a big picture—a multidimensional, complex image “that, first gives perspective to the present by prompting us to take the long view and to look beyond what is happening to what might be going on, and second, allow us to fit present phenomena within a narrative and a polythetic framework” (p. 100). However, a framework is not a kaleidoscope of random patterns. The unavoidable submission to master narratives is both limiting and enabling: without the possibility to synthesize generalizations, our observations would only be individual fragments, but if the notions of historical significance are rigidly scripted in curricula and traditions, our outlook will be limited. Narratives are antennae through which we sense the world, so when the world changes, we must tell new stories to orient ourselves.

Introduction

Literacy has occupied a central position in national curricula since the early days of compulsory schooling, although the curricular form literacy has taken has varied across time and different contexts. On the one hand, the ability to read and write has been argued by governments to be a necessary prerequisite for individuals to function in society; in fact, the UNESCO has since its founding in 1946 maintained that literacy should be seen as a fundamental human right (Wagner, 2011). On the other hand, literacy and its curricular role has also been a highly political and politicized matter; what to teach and how under the label of literacy continues to be used as a tool in the ideological struggle for power and recognition (Blackledge, 2001; Curdt-Christiansen and Weninger, 2015; Luke, 1988, 2004; McKay, 2011). Tensions around literacy have only been made more pronounced due to globalization and the technological developments of the last 20 years, given that these have profoundly altered communication practices and thus have direct implications for literacy curricula.

In this chapter, I discuss curriculum and literacy with reference to two parallel trends that I argue have been affecting literacy curricula across the globe. First, I describe how the field of literacy has seen major shifts in terms of what we understand literacy to be and the implications of this change for school literacy education. In general, this shift is characterized by an expansion and pluralization of the notion of literacy, both in terms of its theoretical treatment in academic scholarship as well as with regards to its practice in everyday communicative encounters. Second, there has been a trend toward the reconfiguration of education in terms of human capital development; in other words, education and schooling is seen as a direct and causal enabler of individuals' earning power (Gillies, 2011) and by extension also as a key driver of national economic progress. This strong economic impetus, coupled with the international educational competition it has facilitated, brought with it a need to standardize literacy both in curriculum and assessment. These two trends, one toward expansion and pluralization, the other toward measurable units and standardization, have led to tensions which ultimately must be managed by those in charge of enacting curricula: teachers and educators.

Expanding literacy

New literacy studies

The notion of literacy as the subject matter of curricula has undergone major shifts in the last several decades. The answer to the question, what does it mean to be literate, has been the focus of intense scholarly discussions whose general direction has been toward pluralization. An important catalyst in this process was theory and research in language and communication that surfaced in the 1970s. On the one hand, functional (as opposed to mentalist) theories of language drew attention to the social motivations for the emergence, organization and development of lexical-grammatical systems (e.g., Fillmore, 1976; Halliday, 1973) while sociolinguists shed light on the social origins of linguistic variation in speech (Labov, 1972). On the other hand, cross-cultural, ethnographic studies of community and home literacy carried out by anthropologists in the 1970s–1980s (Heath, 1983; Street, 1984; Hymes, 1974; Besnier, 1988) revealed fundamental insights about the deeply contextual nature of reading and writing. Shaped by these developments toward a social and cultural understanding of language and communication, literacy came to be recognized as a complex social practice; that is, reading and writing are occasioned by social-communicative needs arising within communities or social groups, shaped by the values, histories and social relations within the group. Forms and technologies of literacy are thus embedded within systems of meaning-making that are fundamentally social and cultural in nature.

This notion of literacy as social practice had significant implications for school literacy curriculum and instruction, particularly within the anglophone world. It directly challenged what New Literacy Studies scholars called autonomous literacy: the idea that reading and writing were discrete, individual cognitive skills detached from their sociocultural context or community of use. As

Street (1995), Gee (1990) argued, such a conceptualization undergirded school curricula and teaching, resulting in “pedagogized literacy” (Street, 1995) which did little to recognize the diverse socio-cultural literate experiences of learners and instead imposed and expected standardized (and supposedly neutral) forms of literacy that served the national interest. School literacy was therefore best described as an ideological practice (Street, 1995) which aimed primarily to foster modes of communication, learning and identities associated with social elites and which reproduced extant social hierarchies.

New Literacy studies scholarship was crucial in highlighting the ideological nature of literacy. In that sense, the pluralization and expansion of literacy was partly a move away from cognitive and individual conceptualization toward a socio-cultural and political one. In addition to the question of what counts as literacy, now the focus was also on whose literacy practices should serve as the model for school literacy. This question has been especially consequential for children whose home/community literacy practices have been traditionally excluded from the school-sanctioned repertoire since those children’s linguistic expertise and identities could not act as resources in the acquisition of literacies that are valued by society. Much subsequent research has therefore explored the home-school literacy connections, seeking ways to highlight children’s funds of knowledge (González et al., 2005) that should be drawn upon in school literacy instruction.

While the issue of class divides and their impact on curriculum, pedagogy and student learning have long been discussed in educational research (e.g., Bernstein, 1990; Erickson, 1987) the question of how out-of-school literacy should inform what happens in school has been formulated and studied from a range of perspectives. For instance, literacy scholars in the 1990s and 2000s were interested in how popular culture as a crucial element of children’s culture and literacy could be harnessed within the school classroom (e.g., Dyson, 1997; Lewis, 1998; Marsh and Millard, 2000; Shegar and Weninger, 2010). Similarly, awareness also grew of the difficulties faced by children from families with languages or language varieties which are vastly different from the standard expected at school. With the global increase in migration in the last two decades, classrooms are becoming more and more diverse linguistically. Thus even in countries where literacy instruction is in a single national or majority language, recognizing children’s multilingual repertoires as a resource has been an important argument for enabling them to gain competence in the language and literacy practices valued by schools (Gort and Sembiante, 2015; Hornberger and Link, 2012). Most recently, the issue of divide has been studied from the perspective of differences between technologically mediated forms of literacy youth engage in for leisure and the lack of inclusion of such literacies in school instruction (Alvermann, 2012).

These developments have had obvious implications for curriculum. The new conceptualization situated literacy within histories and traditions of textual meaning-making tied to social groups and communities. It also recognized values, emotions and identity as implicated in the socio-cultural practice of reading and writing. Further, literacy as ideological practice highlighted how social valuations attached to different forms and norms of reading and writing are intertwined with the relative power various groups have within the social hierarchy, so that learning to read and write in school becomes exclusionary or marginalizing toward those whose non-school textual practices are not reflected in pedagogized literacy. In light of this, curriculum should incorporate and account for students’ home and out-of-school literacy practices as much as possible (Alvermann and Hinchman, 2012). Researchers have also argued for the need to expand the school literary canon to incorporate a wider variety of texts, both in terms of genre (e.g., those from pop culture such as comic books, or fantasy novels) as well as cultural or ethno-linguistic origins of authors (e.g., postcolonial works or migrant literature).

Additionally, the school subject of literacy had to be broadened in order to successfully account for the fact that reading and writing are not simply about encoding and decoding texts; rather, literacy is equally about understanding how texts communicate values and identities through the ways in which they represent the world. Starting in the early 2000s, strong arguments have been made to expand subject literacy to encompass critical and media literacy (Alvermann and Hagood, 2000; Hart and Hicks, 2002) as well as new literacies of the digital era (Lankshear and Knobel, 2003, 2011). The expansion of the school canon through diverse popular cultural, digital and media texts necessitated the teaching and learning of new competencies in addition to what has been termed “traditional literacy”. Media and critical literacy as part of the literacy curriculum should foster the critical reading and evaluation of (new) media texts, couched within an examination of how social context shapes the production of texts (literacy as social practice) as well as providing opportunities for students to engage in text production to explore questions of identity, representation and power (Buckingham, 2003; Hobbs, 2007; Kellner and Share, 2005). These developments were precipitated to a great extent by the publication of a paper that has come to be one of the most significant milestones in literacy theory of the past 30 years.

Multiliteracies

Scholarly arguments for the relevance of popular culture for school literacy was in a way part of much broader developments that were taking place in the 1990s and which had direct consequences for literacy curriculum and instruction. New communication technologies such as mobile phones and email, were becoming widespread thanks to advancements in digital technology. The internet, text-heavy as it was in the 1990s, enabled a range of new multimodal genres and ways for people to connect with others on a scale and at a speed not previously seen, although technological adoption was extremely uneven in those early years. In parallel, conditions of work and life were changing due to a decline in mass manufacturing (in the global North) and the dominance of knowledge-based industries. These changes created new conditions of work and employment as well as new competencies from those seeking employment as knowledge workers, such as communications skills and collaboration (OECD, 2001). As Gee and Lankshear (1995) argued in a more critical vein, a whole new discourse around the new work order and its requisite skills emerged, which was then taken up by educational establishments as rationale to realign curricula in the service of the global capitalist economy.

While literacy scholars were broadly critical of global capitalism and its commodification of communication (e.g., Fairclough, 1999), there was agreement that shifting communication practices had to be accounted for in the theoretical conceptualization of literacy as well as in educational practice. This was precisely the premise of the New London Group (1996) publication titled *A pedagogy of multiliteracies: Designing social futures*. It presented a succinct overview of social and technological changes of the late 20th century and argued for the need to redefine the what as well as the how of literacy education. The group's proposal was first of all motivated by a vision of education where learning benefitted all students by enabling them to fully participate in social, civic and economic activities. To facilitate this access, literacy education had to reflect the diversity and pluralism that characterized literacy practices outside of school:

First, we want to extend the idea and scope of literacy pedagogy to account for the content of our culturally and linguistically diverse and increasingly globalized societies, for the multifarious cultures that interrelate and the plurality of texts that circulate. Second, we argue that literacy pedagogy now must account for the burgeoning variety of text forms associated with information and multimedia technologies.

New London Group (1996, p. 61).

The group ardently advocated the need to de-prioritize language, especially in its schooled, prescriptive and monolingual form, and think of literacy as competence over the myriad modes of representation (visual, spatial, gestural, etc.) available to people to communicate. Central to their arguments about the “what” of literacy was the notion of design. Literacy as social-semiotic practice, according to the New London Group, had to be reconceptualized to highlight its dynamic aspect and transformative potential. On the one hand, we must acknowledge that the tools at our disposal for meaning-making (such as the grammar of language, or conventions of visual communication) are to some extent given to us—what the group called available design. Yet semiotic activity is never simply about strict adherence to conventions; there is always the possibility for agentive deviation or creative deployment of available designs through acts of literacy. This process is termed Designing, again to highlight the dynamic character of reading, writing, speaking and listening, as enabling Redesign: transformed meanings (representations, identities) which themselves become new available designs.

Literacy curriculum as envisioned by the New London Group was then “a design for social futures” (p. 73), prompted by fundamental changes in the social and economic organization of the world, and the kind of social subject schools needed to educate. Instead of hierarchical authority relations, stable knowledge and learning-as-transmission that characterized institutional education in the 20th century, 21st century curriculum must envision learners as agentive, and learning as transformative. As Kress (2000) put it, “Design asks for production of the new rather than replication of the old. Thus putting ‘design’ at the center of the curriculum and of its purposes is to redefine the goal of education as the making of individual dispositions oriented toward innovation, creativity, transformation and change” (p. 141).

Global trends in literacy curriculum

Education as human capital

Literacy scholars, recognizing the fundamental shifts that were taking place in the late 20th century, had a plan for literacy education: to pluralize the notion of literacy and to shift school curricula to embrace the creative possibilities of the diversity that globalization and a new digital communicative landscape brought about. As many of them recognized around the turn of the century, the global capitalist economy rather than national states would shape the direction of education and thus school curricula (Gee and Lankshear, 1995; Kress, 2000).

But in fact, the largely economic reshaping of (public) education began significantly earlier, with the advent and increasing influence of Human Capital Theory (HCT), originally formulated in the 1960s (Becker, 1962; Schultz, 1960). HCT posits a causal link between an individual's level of education and their earning power so that according to the model, more educational credentials will lead to higher levels of income (Gillies, 2011). Moreover, this direct and causal relationship can be scaled up such that a well-educated populace will also translate into higher economic gains at the national level. This fundamentally economic argument for education has been extremely influential for education policy globally (Fitzsimons, 2015). Specifically, it has facilitated the marketization of education in multiple ways. First, once the individual became a form of mobile capital, schooling became a process of capital accumulation; the acquisition of skills, competencies and attributes that are thought to add and increase value. Second, framing education in economic terms gave it an instrumental, transactional valuation: one where cost-benefit analysis will determine which schools one will choose (for their child), which courses, subjects, majors one will enroll in, which languages one will learn. Other motivations for pursuing education (passion, interest, talent) become secondary. Third, entire industries have sprung up around aspects of human capital thought to be particularly valuable on the global market: commercial literacy packages, STEAM enrichment programs, English language schools, coding camps, often offered at very young ages so that kids can “get a head-start”. Fourth, competition, a central driving force of market capitalism, has also become a central characteristic of education both at the individual as well as the national level. League tables and global rankings now sort schools, universities and entire countries according to how well they score on certain standardized measures, giving us supposed objective assessment of the country's human capital potential or the best schools or universities to attend for maximum economic return.

HCT has precipitated the emergence of the educational market over the last few decades where students as customers come to acquire commodified educational goods (skills, competencies, dispositions) in institutions of learning that operate under a management model that is based on accountability to customers, “stakeholders” and the government, who can withdraw funds for under-performance (Ball, 2003; Hursh, 2005). Measurable outcomes and measurable progress are key components of this model because they constitute the basis for comparison across schools, districts and countries. In this regard, international tests of educational achievement such as the OECD’s Program for International Student Assessment (PISA), the International Association for the Evaluation of Educational Achievement’s TIMSS (Trends in International Mathematics and Science Study) and PIRLS (Progress in International Reading and Literacy Study) have been particularly influential not only in facilitating global comparisons but also in directly shaping national educational policy and the direction of education reform (Lewis and Lingard, 2015; 2016 Special Issue of the European Educational Research Journal).

The widespread acceptance of HCT as a blueprint for education policy making had a significant role in reshaping education as a global business enterprise for the creation of human capital to feed the knowledge economy. This process has been largely overseen and managed not by national governments but by an emerging global network of supranational and non-governmental organizations (Ball, 2012; Rizvi and Lingard, 2010). One important impact of these global trends on national policy and curriculum has been toward homogenizing educational purpose, content and quality, irrespective of context or national histories (Zhao, 2015, 2020). Twenty-first century education espoused by global policy-making is a decidedly “employee-oriented education” (Zhao, 2012) in its purpose, comprised of sets of skills and competencies thought to be universally applicable and needed by a 21st century workforce and measurable through standardized tests. What does such a view of education then mean in terms of literacy and curriculum?

Literacy curricula in global times

In the first part of this chapter, I argued that a crucial point for 21st century literacy education from a scholarly standpoint was the need to empower learners to design new social futures. The model of education described in the preceding paragraphs however is in stark contrast with this vision. Indeed, scholars have critically examined the impact of the global trends sketched above on literacy curriculum and instruction and the results are not always encouraging, pointing toward processes of decontextualization, standardization and fragmentation in many cases.

First, and in line with Kress’ (2000) call for a curriculum of communication instead of language or even literacy, communication has indeed been afforded a central place in curriculum debates. In fact, it is frequently cited as one of a number of “C”s, along with collaboration, creativity and critical thinking that make up crucial skills for the 21st century (Battelle for Kids, 2019). However, communication as a curricular component of 21st century education has generally been stripped of its complexity and reduced to the notion of communication skills (Shin, 2016; Weninger, 2019): a set of desirable competencies that are thought to be context-independent, such as how to give a successful presentation or how to construct arguments. Often, communication curricula amount to little more than mastery of the genres of work (Weninger and Kan, 2013), which while certainly valuable, falls far short of lofty goals such as innovation and creativity. Quite the contrary; when we reduce communication to a bundle of decontextualized skills, we are erasing the very contingency and contextual situatedness which makes communication an ambivalent process, always open to possibilities (Fairclough, 1999).

Another important aspect of curriculum development has been the adoption of standards-based frameworks for literacy. In the United States, the Common Core State Standards Initiative was jointly developed by the National Governors Association and the Council of Chief State School Officers and has been adopted by the majority of US states. The Standards, with the tagline Preparing America’s Students for Success, represent core knowledge and skills that all high school graduates in the United States need for college and career-readiness in the two main areas of math and literacy. Similar efforts in the UK and Australia have led, over the past 20 years, to the formulation of literacy benchmarks; essentially standards of achievement formulated as part of a national literacy curriculum. The Council of Europe’s Common European Framework of Reference for Languages (CEFR; Council of Europe, 2001; and the 2020 Companion Volume update) was specifically aimed to standardize educational administration concerning the purpose, content, methods and professional development of teaching and learning languages across Europe. The framework identifies detailed descriptors for various levels of language proficiency in areas of receptive, productive, pragmatic and sociolinguistic competence and has been increasingly adopted in regions and countries outside of Europe, such as Asia and Latin America (Read, 2019).

Literacy curricula today mostly take the form of national and supranational frameworks of standards and competences. Scholars have critiqued individual frameworks on various grounds; but a broader critique of standards-based literacy curricula centers on the observation that they are inevitably accompanied by assessment regimes which have serious washback effects on teaching and learning (Comber, 2012; Hardy, 2015). For instance, despite the CEFR being driven by a “vision of the user/learner as a social agent, co-constructing meaning in interaction, and by the notions of mediation and plurilingual/pluricultural competences” (Council of Europe, 2020, p. 21), the framework is mostly known for its proficiency scales which are used as the basis for assessment and developing national tests (Read, 2019). Standards-based curricula thus must be seen in the broader transformations of language education as a global affair; what is viewed as important knowledge and skill is informed by the needs of global capitalism, gets vernacularized (Rizvi and Lingard, 2010; Weninger, 2017) as local curriculum for the creation of human capital, and is in turn monitored and measured through accountability systems such as standardized tests. At every step of the way, there is a host of educational products being created for an educational marketplace for anxious parents and lifelong learning in the gig-economy.

The implications of these trends for literacy as a curricular subject are quite clear and well-documented in multiple contexts. Despite scholarly arguments and research evidence for the increasing pluralization of literacy as outlined earlier in this chapter, it seems that we are reverting back to the idea of literacy as a measurable asset of individual learners. Given the interlocking of outcome and standards-based literacy curricula with standardized testing, it is no surprise that “as the content of the curriculum moves to match what the tests require, the structure of curricular content knowledge similarly shifts toward the fragmentation demanded by the tests” (Au, 2011, p. 30). Curriculum is always the outcome of a process of selection (Apple, 1979) based on ideological principles. And a literacy curriculum influenced heavily by the need to measure will give weight to those aspects of literacy which are amenable to measurement and have a history of being measured. This means a strong emphasis on (select aspects of) language—as printed, monolingual text—at the expense of multiliteracies.

Perhaps even more subtly, intended curricula are frequently based on progressive ideas about the need for multiliteracies and an emphasis on effective, creative communication. This is certainly what we see in the globally influential frameworks that often incorporate critical thinking, media and research skills as part of literacy. However, by emphasizing results rather than the means (as the Common Core State Standards for English Language Arts explicitly does, for example), we are essentially putting the cart before the horse. In other words, when standardized high-stakes examinations are the primary measures of learning, the enacted curriculum will likely be shaped by what is on the test rather than the philosophical ideas behind the curriculum.

Conclusion

New literacy scholars introduced the expression literacy as social practice in opposition to what they saw as the prevailing cognitive, individualistic view that undergirded school literacy curriculum and instruction. They critiqued this pedagogized literacy as an autonomous or neutral technology that was routinely utilized as an “independent variable” (Street, 1984), measurable on its own as well as how it correlated with or resulted in various societal outcomes. Yet new literacy scholars were by no means the first ones to bemoan the negative effects of psychometric approaches to literacy and the overstatement of literacy’s socially and morally redemptive powers (cf. Graff, 1979). As early as 1921, writers of the Newbolt Report, which was instrumental in identifying the place of English as curricular subject in Great Britain, stated:

Now, as then, there is the danger that a true instinct for humanism may be smothered by the demand for definite measurable results, especially the passing of examinations in a variety of subjects, and if those who are anxious to do justice to English find it so hard to carry out their desire, what is to be expected from those who will remain indifferent?

The Newbolt Report (Board of Education, 1921, p. 55f).

It seems that this 100-year-old concern of those “anxious to do justice” to literacy is unlikely to go away or be resolved anytime soon. The creative potential of literacy as a tool for young people to design social futures, as the New London Group implored, lies in its messy, situated, deeply contextual and pluralistic manifestations. School curricula and instruction that is driven by the need to foster literacy as homogeneous, decontextualized and measurable skills is not going to lead to the transformation that the notion of Design encapsulates, even if influenced by noble ideas about global communication. Such literacy curricula are fundamentally system-preserving, effecting the replication of the old and thus the reproduction of the status quo.

Glossary

- Bildung** The process of formation, as in the formation of the person's character through suitably educative experience
- Canonical concept** A conceptualization that has broad currency in a disciplinary field, and so provides a useful referent for representing as target knowledge in the curriculum
- Confirmation bias** The tendency to pay more attention to data that provides supporting evidence for a conjecture or belief
- Control of variables** The technique whereby the effect of changing one variable (referred to as the independent variable) upon another variable of interest (referred to as the dependent variable) is tested by keeping all other potentially conflating variables constant (i.e., controlled)
- Curricular inertia** Where the merits of a well-established component of the curriculum come to be taken for granted
- Curricular models** The versions of target knowledge that appear in curriculum specifications and which are generally simplifications of the disciplinary knowledge they represent
- Curriculum subject** An identified component of the school curriculum (e.g., science, physics), usually assigned designated slots in the timetable
- Didactic transposition** The process by which disciplinary knowledge is inevitably imperfectly represented through the educational processes of curriculum development and teaching
- Discipline** In part this refers to an area of knowledge, but also the associated assumptions about how knowledge in that discipline is judged and developed, and the methodological techniques and standards, as well as the norms concerning such matters as how findings are communicated and are evaluated within a community of practitioners
- Learning progressions** Research-informed models to inform curriculum design, providing a framework encompassing learning trajectories in a concept area that are judged as viable for learners working over a defined range of grades
- Project-based learning** Curricular activities defined for the learners in terms of a substantive project that groups of students work on over an extended period

Introduction

Science has become established globally as a core aspect of the school curriculum, as is evidenced by the perceived significance of such international comparisons the Trends in International Mathematics and Science Study (Mullis et al., 2019). This article will consider the nature of science in the school curriculum focusing in particular on the theme of what should be included under school

science curriculum in relation to (i) the purposes of science education for all school age learners, and questions of (ii) how science itself is understood, and (iii) how science can be organized within a teaching curriculum (including in relation to “STEM”—science, technology, engineering and mathematics—as a curriculum area).

Three phases of constructing a science curriculum

The construction of a curriculum around any subject area (to form a timetabled curriculum subject) involves the specification of subject matter to be included, which encompasses three sets of considerations (see Fig. 1). “Subject matter” may refer to knowledge (topics, concepts, etc.), but could also mean skills (e.g., accurate weighing with a chemical balance) or attitudes (e.g., to value objectivity in enquiry). School curriculum subjects may be constructed that draw upon knowledge from across formal disciplinary boundaries (e.g., “personal, social and health education,” citizenship education) which offers curriculum developers considerable freedom to define the subject. However, commonly the school curriculum is largely framed in terms of subjects that nominally reflect academic disciplines or groups of disciplines—such as the natural sciences.

Firstly, it is necessary to identify *the scope* of potential material that might be included as falling within the subject area. Here, we might ask: what counts as *science*? (Or, what counts as *biology*, or *astronomy*, and so forth.) Then, there is a question of *selection*. Given that there is likely to be more potential material than can reasonably be included in a school curriculum, decisions have to be made about what to include, and what to omit. That is, which science is it most valuable to teach? That is a judgment that can only be made in the light of a position (whether explicit or otherwise) on the purpose (or purposes) of science education—and may lead to different answers for different groups of learners. However, once a selection has been made from among the potential range of disciplinary material, there is also a further consideration as disciplinary knowledge is often not immediately accessible to school age learners. There is the issue, then, of how the disciplinary content will be *represented* in the curriculum.

Demarcating science

It is tempting to assume that the distinction between science and non-science may be taken for granted, as it may seem that what counts as science is widely recognized. The sociologist Basil Bernstein (1971/2003) suggested that curriculum areas differ in terms of how permeable their boundaries are. In the Anglophile tradition in which he worked, science, with its well-established disciplines and associated learned societies and professional bodies, might be characterized to be a relatively “strongly classified” subject area well “insulated” from other parts of the curriculum, and traditionally a “strongly framed” curriculum area where there has been limited flexibility in pedagogy. It generally seems clear what does, and what does not, fall within its scope—and often what counts as “teaching science.”

However, in some national contexts, reference to “science” in the curriculum might be assumed to include mathematics as a component part of science, whereas these are clearly understood as distinct school subjects elsewhere (see also Fig. 3). Content can be found included in science curricula in some national contexts that would more commonly be considered to fit elsewhere in the school curriculum, such as under geography (Taber and Vong, 2020). This reflects how even in Universities today disciplines such as psychology and geography may be considered to fall partially under the natural sciences, and partially outside.

Despite its ubiquity in modern culture, science in its contemporary sense is a relatively recent invention. The term “scientist” was only introduced in the 19th century. The word science reflects the Latin term “scientia” which refers to knowledge in general. In German today the term Wissenschaft has a much broader meaning than its *nominal* equivalent, “science,” in English. So, whereas, generally, English speakers see “science” as synonymous with the natural sciences (and therefore *not* including the social sciences), the natural sciences would usually be *specified* as Naturwissenschaft in German.

Fig. 1 Constructing the curriculum. From <https://science-education-research.com/teaching-science/the-science-curriculum/>.

The medieval universities of Europe tended to require a common core for all students (before they could progress to the advanced faculties such as law, theology and medicine): grammar, rhetoric, and logic; followed by arithmetic, astronomy, geometry, and music. Although we might recognize astronomy as a science in contemporary terms, it was then a subject largely concerned with practical issues such as determining the calendar, and the modern distinction between astronomy and astrology had not become so clear.

Modern science drew upon pre-existing traditions such as that of natural philosophy and alchemy, and indeed the notion of natural theology (in Christianity, but reflecting a view also widely adopted in Islam) where the study of the natural world was expected to complement and buttress the study of religious scriptures (Grumett, 2009). It is probably not possible to make a clear distinction between science and its historical precursors, nor indeed to offer an account of the precise bounds of contemporary science that would attract universal agreement.

Selecting science to teach

During the 19th century, science subjects such as physics, chemistry, and geology, the latter then having a much higher public profile than today (Bowker, 2005), began to appear in the school curriculum for those privileged to be offered more than an elementary education. During the twentieth century there were debates in various contexts about the amount and form of science education suitable for all or some groups of learners (based on ability judgments, age, or even gender). The sheer extent of knowledge in the natural sciences also grew enormously, making decisions about the selection of content more challenging. Material that has become established in a curriculum may acquire a kind of *curricular inertia*: teachers will know the topic well, effective pedagogy and learning resources exist, a bank of past assessment items considered to test understanding or skill level is available, and so on, and its presence as part of school science may become taken for granted.

Introducing “new” science (which may be seen as having currency in public discourse as well as greater technical, commercial or social relevance) may seem indicated. For example, in the 20th century relativity and quantum theory brought about fundamental shifts in physics, and in terms of our best current understanding of the universe. These topics would seem to have a strong claim to being introduced to at least more advanced school students in order to reflect and represent modern physics. Yet these are considered especially difficult topics due to their counter-intuitive nature and high mathematical content. It might in part be countered that research physics today is *generally* primarily conceptualized and communicated in highly abstract mathematical terms that are necessarily downplayed in school physics, and that the *descriptive*, qualitative nature of the treatment in school science of topics such as heating, electricity, fluids, and light reflects how scientific knowledge must be distorted in order to be accessible to school-level learners when it is *represented* in curriculum accounts.

Other examples of more recent science would be advances in reproductive biology (such as *in vitro* fertilization) and in developing models of climate change. These are less fundamental new areas of science (*cf.* relativity and quantum theory), but with great relevance to people’s lives.

However, introducing new topic areas requires either substituting for some existing curriculum content that will be omitted, or increasing the amount of material to be addressed by teachers and learners. Even when new science seems to *update* existing topics this may not be straightforward. Newtonian mechanics, though now considered displaced by relativity as a theory of the world, is still widely applied. It is said that the Apollo missions that took people to the moon and back managed with calculations based on Newtonian mechanics even though that is now strictly considered an incorrect theory.

Where new material is added to the curriculum without making omissions, the science curriculum becomes increasingly packed with content. Then the time typically available for developing any particular topic is reduced. This makes science more challenging for students who are introduced to an extensive carousel of different topics, each for relatively short periods before moving on (Cerini et al., 2003). This, in turn, is considered to encourage a focus on memorization and recall of key points rather than deep understanding of concepts and engaging higher level skills. This can also be demotivating for the highest achievers (sometimes labeled “gifted” learners) who find little to challenge their thinking and engage them in depth.

This issue of the science curriculum becoming extremely broad but shallow may be avoided if the curriculum is designed from a perspective that puts less emphasis on specific conceptual content and more on other foci (such as skills development, values and attitudes), which aligns with some views of the primary purpose of education.

The science curriculum and educational purpose

Considerations of curriculum choice should be related to the aims of education, as curriculum can be seen as the means of responding to such aims (see Fig. 2). When knowledge was largely viewed as something fixed and transferrable (consider the central place of Aristotle’s corpus in University education and the place of the classics—that is the Latin and Greek classics—in grammar school education over some centuries), education could be seen as the means by which knowledge was passed on, from teacher to pupils, some of whom would later become teachers and pass the same knowledge on themselves. Arguably, such a perspective remained influential into the start of the twentieth century—even in elite institutions (Perry, 1985). Today it is more common in education to reject the notion of knowledge as the kind of entity which can be transferred (or perhaps more accurately copied) from one mind to another, and to see knowledge as personally constructed, albeit usually socially mediated (Glaserfeld, 1989), and being contingent

Fig. 2 Selection of curriculum content should reflect the perceived purposes of the educational program. From <https://science-education-research.com/teaching-science/aims-of-the-curriculum/>.

on the interpretive resources (prior knowledge, intuitions, experiences, sources for understanding similes and analogies, imagery, etc.) available to the learner, as well as the teacher's skill in "making the unfamiliar familiar."

A curriculum specification should then reflect the question "*what are we trying to achieve through this curriculum?*", which will inform not only the *selection* of material but also its *organization*—for example, organizing units according to disciplinary topics, or alternatively, through social issues or everyday contexts (Bennett et al., 2003)—as well as how teaching is organized. It is possible to suggest a number of complementary "drivers," such as the four suggested below, that might motivate different choices of (or priorities for) curriculum content and organization.

Four frames for understanding the purposes of the science curriculum

There are a number of perspectives informing the aims of schooling today. These can be considered complementary as all have merit, but where they indicate different kinds of curriculum specification they also compete for limited resources (for "space" in the curriculum).

The economic driver for science curriculum design

One perspective can be associated with the view that one important role of schools is to prepare young people to take up economically productive roles in society. Science education contributes to the so-called "STEM pipeline" (Cannady et al., 2014) that ultimately provides the scientists, engineers, school science teachers, technicians, medical professionals, technologists and so forth that society needs. Whether education at school level should have an *explicit* vocational flavor is a matter of contention, but schools are expected to provide sufficient candidates prepared to enter further education and training in the sciences.

While this argument has much force, not everyone wishes to enter a scientific or science-based career (and not all of those who seek to do so will be selected). It has been widely recognized for some decades now that designing a science curriculum *primarily* for the minority who will progress in this way is inappropriate (Fensham, 1985): that is, science education that is imposed on all through compulsory schooling should not be designed so that most either fail or are likely to disengage because they perceive it as aligned with vocational aspirations they do not share (Eilks and Hofstein, 2015).

The developmental driver for science curriculum design

Alternative perspectives consider that school science should offer clearer, direct relevance for *all* students (Millar and Osborne, 1998). One such viewpoint is that education is about supporting the formation of the learner to develop into a rounded, self-

confident and balanced person, and this can be supported by a liberal education that offers a wide range of experiences and challenges that can both help the individual develop all aspects of her personality as well as offering a taster of different domains to help her make informed career choices. Through this process a person develops as a unique individual and finds their path in life, something that can be seen as reflecting the German tradition of *Bildung* or formation (Hansen and Olson, 1996) to support self-cultivation.

This perspective might lead us to ask what science might offer to support such personal development. As one example, science is associated with rational thought and science can offer contexts for applying logic, but this will only occur if suitable *activities* are included in the curriculum. Teaching about scientific products, such as theories, does not in itself engage logical thought, unless that teaching encompasses the argumentation that led to the ideas being proposed and accepted (Newton et al., 1999). Such activities might include designing experiments to test hypotheses, drawing inferences by analyzing data, and deducing whether findings support the hypotheses being tested—that is, elements of scientific enquiry.

Widely respected educational theories from psychology suggest that cognitive development requires opportunities to engage in pertinent activities (Piaget, 1970/1972; Vygotsky, 1978). So, for example, research suggests that learners often struggle to apply a basic “control of variables” logic to make inferences from data sets (Kuhn and Dean, 2005). They may notice an *apparent* pattern where a change in a dependent variable seems to reflect a change in the independent variable without taking into account conflating factors due to other potentially relevant variables which are also changing. This perhaps reflects biases inherent to human perception and cognition such as confirmation bias. In the Wason selection task (a seemingly simple task involving four cards, where participants have to decide which cards need to be turned over to test a simple conjecture such as “if a card shows an even number on one face, then its opposite face is red”) most people, even from among samples of highly educated adults, initially fail to appreciate the information needed to logically complete the task (Jackson and Griggs, 1988). Normally developing human youngsters have the potential to understand and apply the principle of control of variables (something fundamental to understanding experimental methodology) but fully realizing this potential may require considerable guidance, support and opportunities.

Science offers myriad disciplinary contexts where experimental tests are designed based on how possible outcomes can logically support or cast doubt upon some conjectured relationship (e.g., the water weed will release more bubbles of gas if the illumination is brighter; the current flow will drop as more lamps are added to a circuit, the metal strip will react quicker in the more concentrated acid, etc.) Such activities need some material context, and in order to be accessible for learners this needs to be a context familiar to them and where they already have relevant domain knowledge—but in principle such contexts could be drawn from across a very wide range of science topics. So, this perspective offers considerable flexibility in selecting science topics to be included in the school curriculum.

It can also be claimed that science offers opportunities for relating to, and appreciating, nature and the environment—but again this depends on the activities undertaken. Perhaps comparing the anatomy of unpleasantly-smelling, pickled, dead specimens of a wide range of animal species *in vitro* (once a common school science activity) can support developing some knowledge, but it may not support the development of a strong appreciation of the living world as much as unobtrusively observing a more modest range of living specimens in their natural habitats.

Clearly, in this regard, there are questions about whether a curriculum subject, science here, offers anything that can be considered unique. Mathematics also potentially offers myriad opportunities for logical thought and argumentation; art offers opportunities for closely observing and so appreciating the natural world; and geography offers opportunities for experiencing the natural environment. Arguably, what is particularly inherent to science is the way it sets up a dialectic process where progress is made through iteration between theory and testing—that is, observations inform new conceptualizations (conjectures) that suggest testing through setting-up further observations which allow refinement of conceptualizations, and so forth—and accordingly enquiry has long been proposed as a core feature of authentic science education (Schwab, 1962).

The cultural driver for science curriculum design

Another perspective sees education as about enculturation: cultural induction into society. This view would suggest that the school curriculum should introduce young people to *all* the major areas of activity that are valued in that society. Science is an important part of culture today, so every young person should be introduced to this aspect of culture. This is not primarily about employability, but in terms of making sense of, and having access to, the (cultural) world in which they live.

It was argued by the English scientist/science administrator and novelist Snow (1959/1998) that there were two cultures in his society—a kind of arts versus science divide, such that it was considered possible to be highly educated and cultured, yet to shamelessly claim complete ignorance of basic scientific ideas. Such a claim seems much less viable in the 21st century, and from this perspective, science education is necessary for a person not to feel excluded from this key strand of their culture. This is not about enabling scientific practices, but a kind of literacy relating to public discourse (Roberts and Bybee, 2014).

This curriculum driver would lead to us asking *what science should all young people be introduced to if they are to appreciate science as a cultural phenomenon*. Perhaps having some notion of what the Higgs boson is, and why seeking it justified the expenditure of such vast amounts of public money might be considered a candidate today. Less esoteric perhaps, it might be asked whether a person should be considered educated in the 21st century if they are unable to engage in informed public discourse about such matters as climate change, loss of biodiversity, or sustainable development.

Similar points may be made about issues of equity and fairness in society and public discourse around such matters as gender, race, and health inequalities. These are matters that clearly invite input from ethics and social science education, but there is also

important scientific background that is needed for engaging in informed debate—and some might suggest that science has a *particular responsibility* here due to a past record of both biased and misused science (Gould, 1992; Harding, 1993).

An obvious example of science that might claim a place in the curriculum here is learning about genetics and indeed epigenetics. For example, race is a social category as from a biological perspective there are not distinct human races—we are all one species, and, if we choose to employ the term in a scientific sense, one race. Yet there are certainly substantial differences in mean frequencies of some important health-related genes in different populations. So, sickle cell anemia is more frequent in people from regions where malaria is endemic, and lactose intolerance is normal in people in large parts of the world (South America, Africa, The Middle East, Southern Asia).

When students are taught about evolution by natural selection they may misconstrue the mechanism as being Lamarckian, as Darwinian inheritance seems to be more counter-intuitive to most people than the (now rejected) inheritance of acquired characteristics, and science educators have developed teaching approaches to address such alternative conceptions (Geraedts and Boersma, 2006). However, it is now recognized that in populations subjected to extreme stresses (such as extended periods of famine or warfare or being enslaved) there may indeed be trans-generational epigenetic effects that continue to disadvantage those born *after* the sources of stress have been removed (Meloni, 2019). There may then be some science topics which though known to be challenging to many learners, deserve a place in the curriculum because of their value in understanding key social discourses that are considered important in the culture.

In a multi-cultural society this cultural driver raises the question of into who's culture learners are to be inducted. Science *seeks* to be an objective means of learning about the natural world that produces culturally-blind knowledge, and is an international enterprise that should in principle be the same regardless of where it is practiced. Yet such an assumption may be problematic in relation to minority indigenous cultures. Often such communities embrace a worldview that does not draw sharp distinctions between science, technology, art, myth and religion. So, such communities value what is often termed traditional ecological knowledge—of a more synthetic nature—which has supported sustainable engagement with the environment for many generations (Ingilis, 1993).

Not only can such knowledge, which may incorporate mythical stories offering allegorical “truth,” seem inconsistent with what is taught in the science classroom, but it may reflect somewhat different values (for example, regarding the acceptability of keeping laboratory animals in cages for ready observation). The key challenge here for the cultural driver is not so much that there may be inconsistencies between accounts or practices arising from these different systems of thought, but rather that inducting learners into science as a *discrete cultural activity* is in itself contrary to the cultural traditions of some groups—indeed the very label “traditional ecological” [sic] knowledge may be seen as an artificial way to demarcate and divide the knowledge of indigenous communities (Kim et al., 2017). This is then an ongoing challenge to developing an inclusive science curriculum.

The civic driver for science curriculum design

A slightly different, but related, perspective asks what science all young people will need to help them in their adult lives regardless of whether or not they are to seek science-based careers. Very few people will be substantially disadvantaged by not being able to use a graduated pipette or not knowing how a transformer works. However, virtually everyone will at some time be faced with decisions about such matters as civic engagement (political action in its broadest sense, e.g., environmentalism) and medical treatment.

For example, a person may be told that they have (or perhaps that their child has) some medical condition where there is an uncertain prognosis, and various treatment options, each with possible side effects. Information provided may be framed in terms of likely and less likely outcomes, with or without treatments. Making an informed decision here will likely depend on some basic scientific understanding. For some people knowledge of the kidneys will be critical in making such a personal life decision, but for others it may be knowledge of the liver, the central nervous system, the endocrine system, the skeletal system, etcetera. This raises the question of just how much material should be specified in a common curriculum when members of society will face unique individual challenges. Rather than indicating a broad survey of a wide range of science topics, this perspective would prioritize deep understanding of a limited set of basic *concepts* that underpin the sciences (perhaps such as conservation of energy; molecular theory; a basic perspective on function and form in biology, and an appreciation of different levels of organization—organ systems, tissues, cells, etc.), complemented with *skills* in confidently accessing and critically evaluating information from across the sciences.

Often, in reaching decisions concerning such real-life dilemmas, no amount of knowledge of the science is sufficient by itself to indicate a definitive best course of action. In the hypothetical case of a serious medical diagnosis, even given all relevant technical information, one might still have to balance how much one would value some likely extra time on earth if choosing some particular recommended treatment with serious side effects (such as chronic nausea, vertigo and drowsiness). In such a context, someone who believed that life was always precious (perhaps sacred) and should always be protected at any cost, and another person who considered the main imperative in life was to maximize the quality of experience to increase pleasure and avoid pain, might reasonably (and completely rationally) make quite different value-mediated decisions when faced with the same choice and the same level of scientific knowledge and understanding. Similarly, someone who had outlived all their close friends and relatives might rationally make a different choice from someone looking forward to the birth of their first grandchild.

As another example, whatever the scientific case for protecting a natural habitat, different people may quite rationally put a different value on this, and have different views about the merits of avoiding habitat destruction when this means a longer commute into town or paying higher taxes. The contribution of the science curriculum would be to prepare learners to engage in public discourse regarding decision-making.

No schooling can provide *answers* to questions such as these, but it can offer experiences to develop *skills* in responding to such socio-scientific issues (Zeidler, 2014) where judgment involves engaging with systems of personal values as well as technical knowledge. The selection of science topics here (beyond those concepts referred to above that are judged foundational for learning *across* the sciences) will be informed by their utility in setting up learning experiences which support students' engagement with socio-scientific decision-making. Choices of context may also have a strong local component—drawing on examples and issues that students will recognize as relevant in their own communities (Sadler, 2011). This might be about the proposed building of a dam; the storage of nuclear waste; the poaching of ivory; the banning of a herbicide, and so forth. Current affairs may offer time-sensitive examples: the COVID-19 pandemic will remain a relevant context for exploring social and ethical issues around the balancing of economic activity, individual freedoms, and disease control measures (informed by knowledge of viruses, vaccination, hygiene measures, individual differences in response to infection, and so forth) in many national settings for as long as this remains a focus of public discourse.

Organization of the science curriculum

These different perspectives on the purposes of teaching and learning science link not only to choices about what to include in the curriculum, but also how to organize science in the curriculum. School science has at various times and in various places been taught primarily: as a program for developing laboratory practice; as an enquiry-based activity to be motivated by and respond to the learners' own interests; as exploration of a sequence of everyday themes or contexts (such as transport, cooking, clothing, health); with a focus on processes (including such activities as classifying as well as laboratory skills); in terms of issues arising from science understood in a social and economic context (Hunt, 1988); as well as in terms of disciplinary topics.

Disciplinary identify

There is a choice of curriculum subject(s)—that is “science or sciences?” One tradition has seen discrete sciences (most commonly biology, chemistry, physics) offered as examination subjects that would be taught as discrete courses. This approach was often most associated with those students being prepared for, or expected to aspire to, higher education. In some secondary school contexts the separation might be quite substantive: different teaching departments with their own designated staff responsible for their specialist subjects. Commonly these sciences would be taught in parallel, but sometimes different science subjects are taught, or offered, at different grade levels.

This tradition has some strengths. Students are given a strong basis to find out if they enjoy and are successful at different science subjects they might wish to select for further study. Teachers can be subject specialists (Reid and Ali, 2020), and teacher preparation and development can have a strong subject-pedagogic focus. Progression within the school can be stronger for learners when a small team of teachers is associated with the same school subject across grades. Where a range of sciences are offered to students as electives they may choose which to study and which to “drop,” giving them some say in their individual program of study (cf. Article 12 of the United Nations Convention on the Rights of the Child).

One objection to this approach is that it is “academic” and designed for a minority of learners (cf. the economic driver discussed above), whereas a broader science curriculum is more suitable for most learners. The term “general science” is sometimes used to refer to a course considered suitable for a wide range of abilities, while other terms may be intended to suggest that academic rigor is being retained while disciplinary content is organized within a single course, whether seeking to identify specific topics from the disciplines (co-ordinated science) or not (integrated science).

Such choices may have significance beyond how science is presented in the timetable. For example, when the English National Curriculum was introduced (Statutory Instrument, 1989) “science” was introduced as a compulsory subject for all learners from ages 5–16 years of age. Although schools could still choose how to timetable the subject (e.g., as separate sciences), “science” was the official school subject, and this had consequences in areas such as staffing (where in many schools an imbalance developed over time, with teachers with biology backgrounds coming to be over-represented compared with those with physics and chemistry backgrounds) and teacher education. Providers of initial teacher education were expected to ensure all those preparing for school science teaching were able to teach across the science curriculum. This had an effect on recruitment in some areas as previously many physics and engineering graduates had prepared to teach physics and saw mathematics as their natural second teaching subject—but now they could only prepare to teach physics alongside chemistry and biology.

A key feature of science is its organization within disciplines which each have their own traditions and characteristics in terms of core commitments, and any authentic science education needs to offer some sense of this (not necessarily, but most easily, done when science is timetabled as separate science subjects). These disciplinary commitments relate to the most fundamental entities and principles, and methodological norms adopted (which become further differentiated within fields within a discipline and to some extent within research programmes within fields).

A common core to the sciences

However, there are also common fundamental commitments across science which reflect the wider nature of science—in particular in terms of values. Science (in all fields) develops by an iterative process whereby observations inform conjectures which motivate

tests and so further observations. Science seeks objectivity. Even though there is much scholarship showing how this can only be an ideal, science values knowledge that is independent of the observer—in principle replacing one trained researcher by another should not influence scientific findings. Science requires honest and full reporting which can support replication and checking of reported results. Again this should be seen an ideal, as in practice there are recognized problems with replicability (Collins, 1992). Scientific authority (again, in principle) relies upon what can be demonstrated and logically argued, not claims based on seniority. Scientists are expected to be self-critical and to always seek alternative explanations for their observations and results. All scientific ideas are open to re-evaluation in the light of new evidence or new suggestions for how to interpret the existing data. Scientists value simplicity, and (internal and external) coherence. The most valued theories are those that encompass the widest range of phenomena with the fewest different concepts and assumptions. Theoretical findings in one field which seem inconsistent with knowledge in other areas of science are considered problematic (they may be tolerated for the time being but contradiction is seen as something that will eventually need addressing).

Scientists are human beings, with their flaws and idiosyncrasies, so it is important for learners to appreciate that the ideals of scientific work are not always met in practice, but this set of characteristics (or something quite like them, commentators will disagree on details) may be considered the normative core of what is to be considered “science,” and arguably the key task of the science curriculum is to support learners in appreciating this nature of science—which is relevant to those seeking scientific careers as well as the majority who will only engage with science as consumers and citizens (Lederman and Lederman, 2014).

If the primary focus of school science is to teach about science as practices of a diverse professional community informed by common scientific values, then this could potentially be achieved by selecting any number of combinations of science topics. Therefore supporting learners in engaging with areas where science impinges on society and personal decision-making can be perfectly consistent with a focus on learning about the core values of science in general.

The flexibility offered by a core focus on scientific values also allows scope to offer some experience of the disciplinary nature of science by ensuring that key concept areas and topics can be included which are associated with different disciplines. Indeed having selected science content according to such a scheme (to teach about the nature of science; to prepare learners to engage with science as citizens; to offer an introduction to the disciplines of science) there is still scope to “package” this as simply science, or to organize the selected topics under distinct discipline-based headings.

The STEM question

This leads to the question of whether school science should itself be subsumed under a broader STEM monicker (Chesky and Wolfmeyer, 2015). A school science department teaching its curriculum subject(s) could be part of a STEM faculty as an administrative arrangement which need not impact on the curriculum presentation itself. However, a strong argument for going beyond this relates to the artificiality of the common school curriculum structure, where learners experience a constant rotation around timetabled slots reflecting different subjects treated as knowledge “silos.” School learning is experienced in discrete aliquots (of perhaps an hour, sometimes less) before moving to a completely different topic in a different subject where there is no attempt to acknowledge or link to what students were doing just before. This compartmentalizes learning and prioritizes “academic” knowledge mainly useful for passing examinations.

A different approach would be to organize the curriculum in terms of more authentic activities where learners engage with projects over extended periods (as is more likely in the world of work) and where problem-solving draws upon whatever areas of knowledge are relevant to the task in hand (Rennie et al., 2012). STEM offers an opportunity for setting up such challenges where students have to solve problems, and build solutions, and where they will learn science and apply mathematics in the context of a realistic challenge. A team of learners might be allocated a sequence of half-day sessions to work on a particular “STEM” challenge.

Such an approach can potentially address some of the criticisms of school learning as being too divorced from the world of work, and involving a great deal of learning for its own sake. There is certainly much to be said for project-based teaching that leads to outcomes that seem tangible to learners (solving a problem in the local community; or at least developing something to be presented to a wider audience) although that can also be undertaken within “science” or specific science subjects.

While it is commonly argued that much groundbreaking work in science, medicine and technology today does take place in inter-disciplinary teams, by definition these teams can only exist because they bring together complementary specialists trained within different disciplines, and this is therefore of itself a weak argument for reorganizing education on such lines. A potential problem of moving to STEM as the subject *within which* science will be taught is staffing. Would the course be taught by an inter-disciplinary team or would “STEM” teachers expected to work across the constituent areas be needed. In most national contexts the latter option would require major changes in teacher preparation and development (which would only be sensible if a strong commitment to a permanent shift in his direction was made). The former option sets challenges within schools—how does one timetable STEM accordingly? One possibility is to block timetable so that a number of school classes work with a team of teachers with different specialisms—but realistically this also requires substantial shared teaching spaces that encompass laboratory, workshop, greenhouse, seminar areas, etc. A less revolutionary possibility is that classes move between specialists as timetable slots within the “STEM” subject periods—but this loses much of the potential flexibility of the interdisciplinary approach. There are considerable practical challenges here that are only worth addressing if moving to genuine “STEM” teaching was considered to justify this.

Another argument might be that STEM as a school subject offers learners a chance to see how science and mathematics can be applied—which is important for many learners who may fail to see the relevance of learning the subjects for their own sake. Yet if

science and mathematics were only taught in this way then a potential gain in terms of relevance could be at a cost of a failure to appreciate the true natures of mathematics and science as cultural practices in themselves. The application of science is not the practice of science. If we want learners to appreciate science as a cultural activity, then they should study science as a school subject (or some sciences as school subjects). While science and mathematics are fundamentally different in some senses (mathematics manages with deductive logic, relates to ideal entities, and involves genuine proofs; science always involves inductive as well as deductive logic, always has an empirical referent, and only offers provisional knowledge open to re-examination), they share putting a high value on new knowledge for its own sake without *requiring* buttressing by real world application. In this way they are quite different in nature from engineering and technology. Fig. 3 caricatures the three main areas of STEM at school level, showing that they all require the creative use of imagination, but for different purposes—and so their imaginative products are evaluated in different ways: to be internally consistent; to match (interpretations of) empirical data from the natural world; and to attain a practical end.

That need not mean there is no place for integrated STEM work. There may be great value for learners who study separate school subjects of science/the sciences, mathematics, technology periodically experiencing collapse of the normal timetable to engage in substantive authentic cross-curricular projects that involve applying their learning. Students then experience the diversity of different curricular traditions with specialist support, but periodically also engage with motivating scenarios where their learning can be applied, consolidated, and developed, without the constraints of the usual discontinuous timetable and the artificiality of disciplinary boundaries.

Differentiating the curriculum

Decisions about what to include in, and how to organize, the science curriculum may be customized for different groups of learners. It has sometimes been the case that “general science” and more contextualized (theme and issue based) science courses have been seen as more suitable for lower achievers, and separate sciences arranged around traditional disciplinary topics more appropriate for the highest achieving. Indeed, sometimes science courses for less academic groups have been framed as applied science (sending an

Fig. 3 Caricatures of science, mathematics and technology illustrating the fundamental differences in their natures. From <https://science-education-research.com/teaching-science/stem-education/>.

unwanted message about the relative status of engineering and technology). Yet, the considerations raised by the different drivers (see above) often apply across the ability range: indeed, learning to engage effectively in socio-scientific decision-making and appreciating the nature of science may be seen as requiring (and supporting the development of) higher levels of intellectual development (Taber, 2016).

Curriculum progression

There is a good case for modifying the nature of the science curriculum experience as students pass through their school career, reflecting how they mature and incrementally acquire experience of the natural world and on-going teaching. In early years education, for example, where teachers often lack formal qualifications and confidence in science, a focus on developing process skills (observing, recording, forming questions, etc.) in the context of nature study, and productive activities such as tending a garden, may lay important groundwork for later learning of formal concepts and theories (Taber, 2019a). The Japanese approach may offer a useful model here (Sumida, 2013). As an illustration of principle, Fig. 4 presents one model of how the science curriculum can be organized around different foci at different stages of schooling (very roughly as primary, middle and secondary phases) to better fit the interests and capabilities of learners of different ages.

Developing curriculum models to represent science

It is not usually the case that canonical knowledge can simply be selected and included in the curriculum “as is.” “School science” is not simply “science” transferred into a school context, but is rather a representation of it—something that may be more obvious in national contexts “such as German, Norwegian, Danish, and Japanese, [that] have different words to refer to science as an academic discipline and to science as a school subject” (Jenkins, 2007, p. 278).

For one thing, the referent for representation in the curriculum may need to be clarified. It may not be so easy for curriculum developers to unambiguously identify *canonical* knowledge in the sense of what scientists (as a community) mean by, for example, “an electronic orbital” or how scientists (collectively) understand “gravity.” In areas where research is currently active there may not be a single agreed “state of current knowledge.” In regards to areas of scientific knowledge that seem currently settled (and *strictly* all scientific knowledge is provisional in the sense of being open to be revisited), there will often be a historical sequence of models or theories. Some of these may now have uncertain status given that many models or accounts which have been strictly supplanted by more sophisticated (and so more difficult to understand and apply) models or accounts (i) are often retained by scientists for use in those contexts where they are considered to work well enough (e.g., Newton’s laws of motion); (ii) may have become partially incorporated into hybrid accounts included in textbooks (Justi and Gilbert, 2000).

As one example, it is not entirely clear if the canonical understanding of the acid concept should be considered as one particular conceptualization (the Lewis model) or a complex of several models (e.g., including the Brønsted-Lowry model) selected from pragmatically according to context. Specialists in a scientific area may not all entirely agree on such matters. In this sense the notion of canonical concepts may be considered as a useful fiction (Taber, 2019b). That is, it is helpful to talk of the placeholder of “the canonical account of a concept” as a referent when discussing curriculum design, without necessarily expecting to identify a version of the concept that attracts consensus among the scientific community. Such a position is not so alien to science itself which operates with such referents as non-existent “ideal” gases, and “laws” that are strictly never empirically followed (such as Raoult’s law), frictionless surfaces, point masses, and so forth.

Even when something can be identified as “the” scientific account of some topic adopted by those currently working in that area of science, it will likely be too complex and abstract for including in the school curriculum. Again, science itself is used to dealing with such situations by developing simplifying models that are useful for communicating ideas and inspiring testable hypotheses. Curriculum development also requires modeling of the science through the use of approximations and simplifications to provide “target knowledge” (i.e., that which it is hoped students will master) that can be engaged with, and understood, by learners at some specific level of cognitive development (Shayer and Adey, 1981). So, for example, if it is decided that the curriculum for a particular grade level will include learning about elasticity, acids and cell division, then this implies not the current scientific accounts *per se*, but specific *curricular models* of those accounts that will *represent* the science as it is to be taught at that level.

This is one area of ongoing scholarship in science education curriculum development, where curricular models are actively developed and proposed. The Institute of Physics has published an approach to teaching energy (an abstract, but foundational, concept where substantial learning difficulties have been documented) for 11–14 year old learners (Ireson, 2006). Specific teaching models have been developed to help move student thinking toward target knowledge, such as the “electronium” model of electric current intended for use with upper secondary (c. 18 year old) students (Buddle et al., 2002). This model is more sophisticated than the teaching models commonly used to introduce electrical circuit concepts to younger learners, which are based on analogies with familiar phenomena (Taber et al., 2015). This difference reflects ideas about progression in learning, and Bruner’s (1960) notion of the spiral curriculum. For example, target knowledge of the components of a plant cell at one grade level might be limited to a very small number of core elements each identified with a principal function, and then at higher grades further components, and more pluralistic accounts of their roles within the system, would be added to build up a more nuanced understanding.

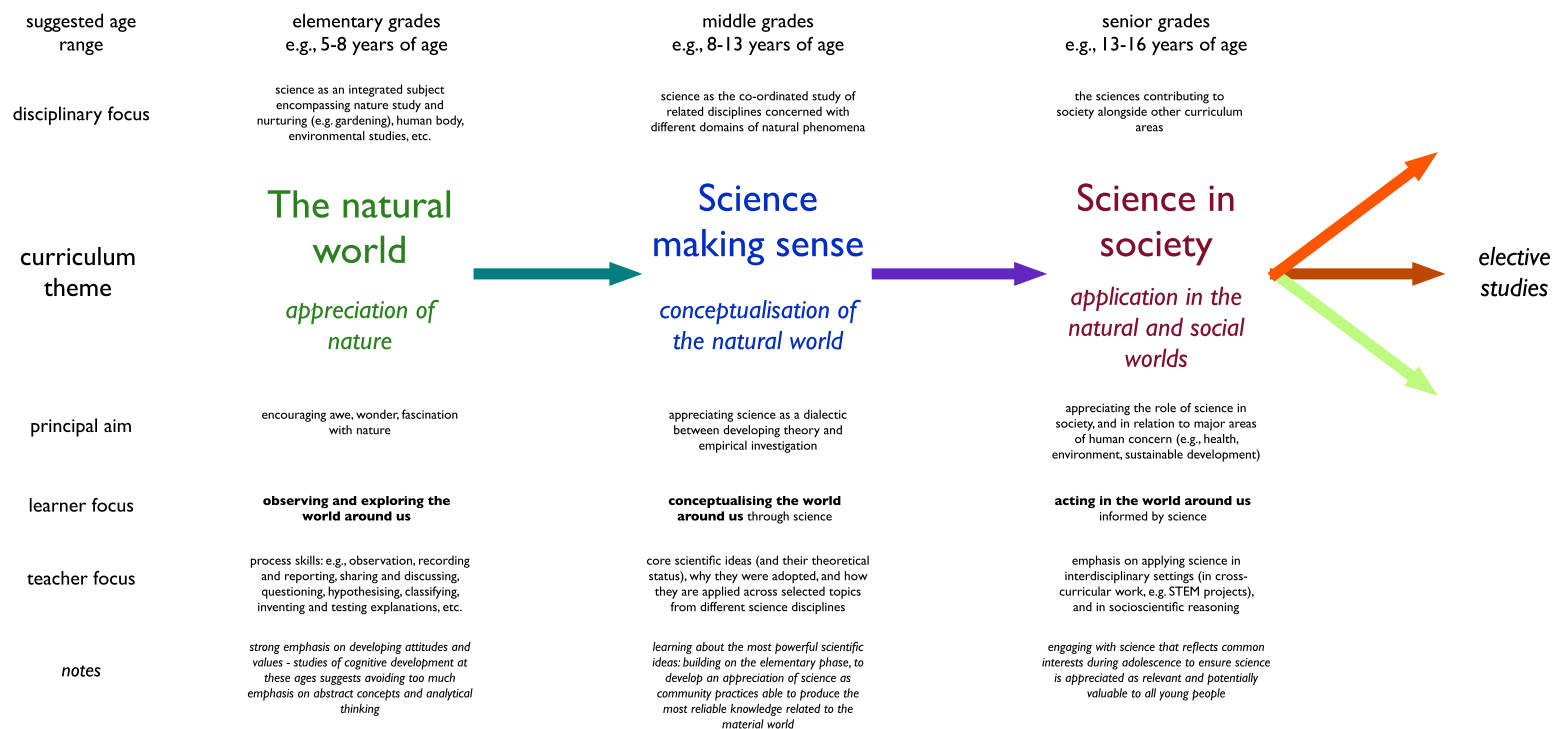

Fig. 4 An example of how the focus and nature of the science curriculum could shift across a learners' school careers reflecting their developing intellect and interests. From <https://science-education-research.com/teaching-science/the-science-curriculum/>, after Taber and Vong (2020), Fig. 2.

Fig. 5 Representation of a “learning progression”—a type of model to support curriculum development informed by research into learners’ ideas and studies of conceptual development. Figure from <https://science-education-research.com/learners-concepts-and-thinking/learning-progressions/> after Fig. 3, Taber (2021).

Learning progressions

This approach has been developed in recent years in an active research programme to develop tools referred to as “learning progressions” to guide the development of curriculum (Alonzo and Gotwals, 2012). While there is some ambiguity in the how the term is used (Taber, 2021), the approach seeks to understand optimal routes to building up more sophisticated target knowledge over successive school grades informed by the extensive literature on topic-specific learning difficulties and common alternative conceptions (see Fig. 5).

The representation of disciplinary knowledge in curriculum is inevitably distinct from what it is intended to represent. Curricular models deliberately simplify canonical content, and teaching models adopted in the classroom may further simplify target knowledge or represent it in more familiar, less abstract terms.

Even if some identified element of scientific content was considered suitable for including in the curriculum without deliberate simplification and modeling, that “element” would be excised from its wider context of historical development, scientific practice, and the embedding network of other “elements” of scientific knowledge against which it is understood and enacted by practicing scientists. Therefore, even when there is no deliberate attempt to modify the science to be taught, there is always a process of “didactic transposition” (Chevallard, 1989) which means that the knowledge *as presented in teaching* is inevitably a *representation* of the referent scientific content.

Defining curriculum	327
Historical perspectives of curriculum and social studies	328
Contemporary perspectives on curriculum and social studies	329
Conclusion: future directions for social studies curriculum	330
References	331

The social studies curriculum sends powerful messages to students and communities about how they should understand themselves. Pinar (2004) wrote that “The school curriculum communicates what we choose to remember about our past, what we believe about the present, what we hope for the future” (p. 20). This is particularly true with social studies curriculum. When we think of the subject areas that are most associated with social studies, such as civics, history, geography, and economics, it becomes evident that these subjects communicate a worldview of the past, present, and future. As curriculum is implemented in schools, students can develop a better understanding of communities ranging in scale from the school to the globe. The National Council for the Social Studies (2022) in the United States explains that “the primary purpose of social studies is to help young people develop the ability to make informed and reasoned decisions for the public good as citizens of a culturally diverse, democratic society in an interdependent world” (emphasis in original, para. 2). Through a better understanding of the past, present, and future, the social studies curriculum emphasizes the need to increase student understanding of citizenship, democracy, multiculturalism, and the globe.

Because there are limitations on the time and resources devoted to social studies education in classrooms, decisions must be made about how to select from the vast universe of knowledge available. The results of these decisions communicate to students, educators, and communities what knowledge is of most value. Conversely, these decisions communicate what knowledge is of least value and not part of the social studies curriculum. Eisner (2002) described what is not included in the curriculum as the null curriculum. Historical and contemporary struggles over the social studies curriculum reform reside in what perspectives, individuals, and communities are portrayed. By including or excluding some individuals and groups from narratives, for example, the social studies curriculum can send powerful messages to students, educators, and communities about who is valued and who is not.

Due to a limited amount of instructional time in the school curriculum, the choices of the individuals, groups, and perspectives become central to the design and implementation of the social studies curriculum. Unfortunately, the social studies curriculum is often a reflection of inequitable power relations in society because dominant individuals and groups often use the social studies curriculum as a way to construct and maintain ideologies that benefit these dominant individuals and groups (Apple, 2018). When subjects such as civics and history reflect these ideologies, students are sent powerful messages about what individuals, groups, and perspectives are of value, as well as which ones are of little value and not worthy of inclusion (Au, 2012; Au et al., 2016; Camicia and Knowles, 2021).

This chapter examines curriculum and social studies education by first defining curriculum in general. There are many ways to describe curriculum, so it is important to provide a general description that can converge on a more specific discussion of social studies curriculum. As the introductory paragraph communicates, it is helpful to understand curriculum as representing a worldview or ideology. Next, I examine social studies education specifically. Because the universe of information involved with social studies subjects is vast, a thematic focus can help with this examination. I conclude the chapter with a discussion of current and future directions in social studies curriculum.

Defining curriculum

Perennial struggles to define the qualities and scope of “curriculum” have ebbed and flowed throughout the history of the United States (Kliebard, 2004). While it is beyond the scope of this chapter to develop a comprehensive historical account of curriculum and its reform, it is important to provide an operational description as a foundation for the rest of the chapter. This will provide a backdrop for understanding why social studies curriculum has been particularly contentious throughout its history. While many mistakenly attribute “instructional materials” or “instructional standards” to “curriculum,” these are only a partial understanding of the qualities and scope of the term “curriculum.”

The difficulty involved with defining curriculum is in the expansiveness of its facets. [Flinders and Thornton \(2013\)](#) capture the challenge posed by describing curriculum writing:

Even a simple definition of “curriculum” such as “what educating institutions should teach” compels answering a vast, possibly overwhelming, set of questions including: what subject matter should be selected and by what criteria, how should the subject matter be organized, to whom should it be taught and by what methods and with what materials, how is it most effectively learned, and how might we judge the success of the undertaking. No one is an expert on the entirety of this still incomplete set of questions every curriculum designer answers, whether directly or tacitly (p. ix).

There are at least three aspects of this description. First, it is apparent that there are multiple facets of curriculum design such as criteria of selection, which could involve the selection of aspects ranging from instructional materials to instructional methods. Second, there are individuals positioned differently in relationship to the curriculum. What are the relationships between students, and what are the relationships between students and educators? For example, does the curriculum reflect authoritarian or democratic relationships between the individuals who experience the curriculum ([Camicia and Si, 2021a](#); [Riddle and Apple, 2019](#)). Third, there are individuals and groups who make decisions about these different considerations. The three aspects above illustrate the complexity of considerations involved with curriculum. Because there are different individuals and groups that make decisions about what to include in the curriculum and what will be part of the null curriculum, the network of power relations in society at large is mirrored in the curriculum.

Curriculum is difficult to describe because it encompasses both explicit and implicit objectives and contexts. While daunting because of the scale and complexity involved with describing curriculum, [Beyer and Liston’s \(1996\)](#) provided a helpful list of questions that reflect the considerations about curriculum that I have included to this point:

1. What knowledge and forms of expression are most worthwhile?
2. What is the relationship between the knowledge embodied in the formal curricula of schools and those who are involved in enacting it?
3. What types of educational and social relationships are required or desirable in order to facilitate curricular experiences?
4. How do larger social, political, and institutional contexts affect the experiences students have with curriculum?
5. What are the implicit (and explicit) conceptions of democracy within the curriculum?
6. What are the implicit (and explicit) visions of students’ social, political, and economic futures, and how does curriculum prepare students for those futures? (pp. 218–219)

These questions serve as a heuristic for understanding and examining curriculum. Returning to [Pinar’s \(2004\)](#) definition of curriculum as a reflection of the intentions for understanding the past, present, and future, it is easy to see how Beyer and Liston’s questions reflect this. It is also easy to see how social studies curriculum might connect to these questions because social studies topics such as civics, geography, history, and economics connect past, present, and future concerns for our communities. I next examine social studies curriculum more specifically.

Historical perspectives of curriculum and social studies

There have been perennial struggles over how to frame social studies curriculum. Because the social studies curriculum has had a primary objective of developing informed citizens, the rationales for curricular reform have centered upon the types of communities we want to develop ([Camicia and Franklin, 2011](#); [Camicia and Knowles, 2021](#)). It is beyond the scope of this chapter to discuss a detailed history of social studies curriculum and its reform, but there are numerous accounts that go into more detail (e.g., [Evans, 2004](#); [Hertzberg, 1981a,b](#); [Lybarger, 1991](#); [Thornton, 2008](#); [Woyshner and Bohan, 2012](#)). The origins of social studies education is usually associated with the [National Education Association’s \(1916\)](#) report that placed citizenship education and history education as the primary focus of social studies curriculum in the United States ([Ross, 2006](#)). Other subject areas have been included over time, and there have been multiple reform movements related to progressive and critical orientations ([Kliebard, 2004](#)).

Within this history, as well as currently, one of the main themes is a struggle between an orientation of social studies toward a *social science* approach or a *social education* approach ([Thornton, 2005, 2008](#)). The social science approach emphasizes disciplinary boundaries as they mirror academic subject areas at the university level. While drawing upon other disciplines, the social science approach places a discipline such as geography centrally, as well as a course entitled “Geography.” The disciplinary approach focuses upon a conception of community where students gain an increased understanding of each discipline to better understand the world.

In contrast, the social education approach blurs disciplinary boundaries in favor of the needs of students and society ([Hertzberg, 1981a](#); [Thornton, 2008](#)). [Thornton \(2008\)](#) described the social education approach as “identifying the individual and social demands of associated living and then deciding what material from the social sciences (and collective material) is relevant to those demands” (p. 20). The social education approach focuses upon a conception of community where the goal is to examine topics and issues that are of importance to community members. In this approach, students play a central role in choosing these topics and

issues. As Thornton noted, these two approaches are not mutually exclusive, and there is a blurring of distinctions. These two approaches and the blending of these approaches in social studies curriculum communicate a stance on what knowledge and worldviews are privileged.

Historically, in the elementary grades, the expanding horizons (Wade, 2002) or expanding environments (Akenson, 1989) model has guided much of the scope and sequence of social studies curriculum in elementary grades across the United States. Wade (2002) described this model and its expanding scope for each grade as: “kindergarten-self, first grade-family, second grade-neighborhood, third grade-community, fourth grade-state and/or regions, fifth grade-United States, sixth grade-Canada and Mexico” (p. 115). As an organizing principle for social studies curriculum, this model emphasizes a worldview where children experience the world from one location and expand out from what they know to regions with which they aren’t familiar.

Unfortunately, the expanding horizons model in elementary grades social studies curriculum makes multiple problematic assumptions about the lived experiences of students in elementary grades. The assumption that children start with what they know in the location they grow up in is challenged by human migration, where students often experience multiple communities and places on the globe from a young age (Camicia and Saavedra, 2009; Saavedra and Camicia, 2010). A social studies curriculum that emphasizes the expanding horizon model risks excluding the experiences and perspectives of students in classrooms that have traveled and lived in different regions and parts of the globe. This is particularly problematic when we understand that one of the primary goals of social studies is to help students understand global interdependence. The exclusion of students’ perspectives that involve firsthand experiences of different locations on the globe harms these students because their knowledge is not valued, and this exclusion denies the rest of the students knowledge of global interdependence.

The expanding horizons model provides an illustration of how dominant ideologies and worldviews often guide social studies curriculum and reinforce social inequalities found in society at large. In addition, the expanding horizons model does not appear to be responsive to the realities of increasing media access and social media usage among elementary-level students. Although this model is ubiquitous in the United States, Wade (2002) noted that there are other alternatives, such as the “Toward the Common Good (TCG)” (p. 120) model, where the elementary level scope and sequence are based upon TGC themes. Wade proposed that these themes could be people, environment, exploration, conflict, democracy, human rights, and interdependence in kindergarten to sixth grade, respectively. Rather than an exclusionary force in social studies curriculum, the TGC model could serve as an inclusionary force by increasing the range of perspectives in the elementary grades.

The thematic approach is used in many of the current standards in social studies curriculum in the United States. These include the following themes, which are guidelines for each grade, K-12: Culture; time, continuity, and change; people, places, and environments; individual development and identity; individuals, groups, and institutions; power, authority, and governance; production, distribution, and consumption; science, technology, and society; global connections; and civic ideals and practices. These ten themes guide curriculum design and implementation at each grade level, and the themes are not mutually exclusive. Students examine one or more of these themes drawing upon the social sciences and other forms of information.

Contemporary perspectives on curriculum and social studies

Many of the historical perspectives of social studies curriculum continue today. In this section, I start by examining current descriptions of social studies curriculum, which are multifaceted and complex. As mentioned above, curriculum, in general, has many facets, but social studies curriculum multiplies these facets due to the number of disciplines included under the umbrella of social studies education. Next, I examine some contemporary perspectives that present opportunities for change and social justice. The current description of social studies reflects the expansiveness of social studies curriculum. According to the National Council for the Social Studies (NCSS) (2022) in the United States:

Social studies is the integrated study of the social sciences and humanities to promote civic competence. Within the school program, social studies provides coordinated, systematic study drawing upon such disciplines as anthropology, archaeology, economics, geography, history, law, philosophy, political science, psychology, religion, and sociology, as well as appropriate content from the humanities, mathematics, and natural sciences. The primary purpose of social studies is to help young people develop the ability to make informed and reasoned decisions for the public good as citizens of a culturally diverse, democratic society in an interdependent world.

(emphasis in original, para. 2).

This description illustrates the interaction of the two social studies curriculum approaches described in the previous section, the social science approach and the social education approach. While the social science approach is included, the National Council for the Social Studies (2022) description starts and finishes with an emphasis on civic competence. This indicates a social education approach because civic competence requires solving problems that are of importance to students and their communities. In other words, students as decision-makers are placed centrally within the learning objectives of social studies curriculum. In addition, the last sentence provides a view into current and future directions of social studies by describing students as citizens navigating “a culturally diverse, democratic society in an interdependent world” (emphasis in original, para. 2).

The foci of cultural diversity, democracy, and global interdependence in social studies curriculum as areas of emphasis create opportunities for students to gain nuanced understandings of different types and scales of community. Since community is a central aspect of citizenship, these areas of emphasis can provide guidance for curriculum development in the areas of multicultural education (e.g., Au et al., 2016; Banks, 1996, 2004; Banks et al., 2005; Castro, 2013; Ladson-Billings, 2004; Moll and González, 2004; Takaki, 2012) education for democracy (e.g., Camicia and Knowles, 2021; Dewey, 1966; Gay, 1997; Gibson, 2020; Hess and McAvoy, 2015; Lo, 2017; Ochoa-Becker, 2007; Pace, 2015; Parker, 2004; Riddle and Apple, 2019; Westheimer and Kahne, 2004), and global education (e.g., Abdi and Richardson, 2008; Andreotti, 2011; Banks, 2017; Becker, 2002; Gaudelli, 2013; Hanvey, 1976/1982; Merryfield and Subedi, 2001; Myers, 2006; Osler, 2015; Oxfam, 2006).

A read of the titles of the works cited above supports the idea that democratic citizenship, education for democracy, multicultural education, and global education are conceptually linked. They are linked through an emphasis on perspective consciousness and increasing perspectives through increasing inclusion. With this in mind, the emphasis upon identifying exclusions in social studies curriculum has been a significant theme of social studies research and curriculum development (e.g., An, 2016; Anderson and Metzger, 2011; Bickford, 2017; Brown and Brown, 2010; Busey and Walker, 2017; Camicia, 2016; Eargle, 2016; Hawkman and Shear, 2020; Journell, 2009; Shear et al., 2015).

Whether social studies curriculum follows a social science approach, social education approach, or a mix of the two, an emphasis on increasing perspectives in the curriculum addresses the democratic mission of schools to educate citizens within the contexts of multicultural and global communities. As the sections above have illustrated, social studies curriculum contains a vast universe of possibilities, approaches, and pedagogies. However, a focus on increasing perspectives is an increasing priority. When framed as a way to educate citizens to participate in democratic communities, an emphasis on increasing inclusion can be a way to increase the legitimacy of the social studies curriculum. Inclusion is closely connected with democratic legitimacy because democratic governance relies upon the inclusion of individuals, groups, and perspectives in this governance. In the next section, I conclude this chapter with considerations of inequitable power relations in society, a lens for inclusionary and exclusionary forces in curriculum.

Conclusion: future directions for social studies curriculum

As Beyer and Liston's (1996) questions prior to this section indicate, social studies curriculum is not designed and implemented in a vacuum. Instead, people are positioned differently in relation to the curriculum, and the curriculum is embedded in different socio-cultural and political contexts (Apple, 2018; Camicia, 2016). When the curriculum is portrayed as a neutral set of facts that are settled knowledge, students are denied an understanding of how knowledge is constructed in society and social science communities. Knowledge in such communities constitutes a political struggle between different understandings of the past, present, and future. By designing and representing social studies curriculum as neutral, curriculum designers present students with an apolitical view of the world. This is ironic when we consider that the stated objectives of the social studies curriculum involve civic education and political involvement in various communities.

An apolitical stance places higher value on authoritarian rather than democratic governance (Camicia and Si, 2021a). Apple (2018) pointed to the limited treatment of social movements in social studies curriculum as an example of how curriculum presents students with inaccurate perspectives on how society changes. Camicia and Si (2021b) examined social studies curriculum standards across the United States. They're analysis found the frequencies of social movement inclusion was extremely low in most states. By focusing on change from those in power rather than from individuals in society and their involvement in social movements, inequitable power relations are constructed and reinforced. Instead, the social studies curriculum needs to help students examine inequitable power relations in society and the ways that they can change their communities for the better with this increased understanding.

In conclusion, there are multiple directions that social studies curriculum can reform. Since "the primary purpose of social studies is to help young people develop the ability to make informed and reasoned decisions for the public good as citizens of a culturally diverse, democratic society in an interdependent world" (emphasis in original, para. 2), the social studies curriculum needs to emphasize education for democracy. Democracy in this sense is not reactionary but revolutionary (Camicia and Knowles, 2021). Democratic governance requires students to make informed choices drawing upon the knowledge from multiple disciplines.

The current national social studies standards emphasize an inquiry-based approach to social studies curriculum (National Council for the Social Studies, 2013; Swan et al., 2018). This is a good place to build upon since there is an emphasis upon multiple perspectives on topics and issues. This can serve as a point of departure by considering some of the references included above, which focus upon increasing student understanding of multiculturalism, democratic governance, and global interdependence. By valuing the knowledge that students bring to classrooms and increasing their awareness of multiple perspectives, students can build their understanding of how to solve problems in and out of their communities.

Although increasing the range of perspectives in social studies curriculum is a great start, increasing perspectives on topics and issues of shared concern is not enough. Perspectives in society are not valued equally, and to treat them as equal reinforces inequalities in society. Instead, social studies curriculum needs to locate different perspectives within networks of power relations. With the increasing movements toward authoritarianism and other forms of oppression, social studies curriculum needs to draw upon multiple sources of knowledge. This knowledge can emanate from students, communities, or social studies disciplines. But principles of democratic governance and understandings of inequitable power relations provide students with the tools necessary to place various perspectives within a social justice framework (Camicia and Knowles, 2021).

Introduction

Curriculum, *Didaktik*, and *Bildung* represent three essential cornerstones of public schooling in general and teaching and learning in schools in particular. They are tightly related to each other and mutually dependent. Originating from a central European, mostly German discourse, they stand for a framework that has characterized schooling in Europe and beyond for almost two centuries, although their origins can be traced back to ancient philosophy and history. In a first step, this contribution presents the three phenomena by revealing their interrelatedness and some common grounds. In a second step, the article discusses how the recent trend of competence based curricula changes and affects the traditional concepts of *Didaktik* and *Bildung*. In a third step, current issues and future questions and tasks for research are presented.

Since the three terms curriculum, *Didaktik*, and *Bildung* refer mostly to theories originating from German, the translation of the terms into English is problematic. While “curriculum” is often used in research publications as a general term that also comprises the German concept of *Lehrplan*, the terms *Didaktik* and *Bildung* in fact do not have any equivalences in English. Each of the following sections briefly amplifies the challenges given with respect to the terms and their translation into English.

Curriculum

Curricula in terms of syllabi are a societal agreement that declare what knowledge a society considers relevant to be taught to its future generation in school and that should assure that societies preserve their identity and existence throughout generations (Hopmann and Künzli, 1994). In a German tradition, curricula (in German: *Lehrpläne* (plural), *Lehrplan* (singular)) deal with the what, when, and how of teaching and learning and specifically refer to a policy document that displays content descriptions for different subjects and grades in schools and in many cases a general description of values and principles that apply to the schools in the respective nation state. In contrast to this, the English term *curriculum* is more comprising and less specific by referring to practice in terms of what happens in a classroom, what is planned by the teacher, and what is expected to be the outcome of a class. The comparative research project “Didaktik meets Curriculum” has defined the term “Didaktik” as the comparative unit to the term “curriculum” (Gundem and Hopmann, 1998), which points to the different scope of curricula compared to the term *Lehrplan*. Even if the curriculum and *Lehrplan* are in fact no synonyms (Horlacher, 2018) and due to practical reasons, I will—in line with other research articles—use curriculum as a more comprising term that also includes syllabi in terms of *Lehrpläne*.

In the German speaking countries, curricula are steering tools in terms of laws that are not only provided to public schools, but that are developed as a subject of public deliberations. They gained significance within the emergence of the European nation states in the late 18th and 19th century. This process was accompanied by a strong desire and need to create capable and loyal citizens, not least by building an efficient school system controlled by the state and its administration body (Hopmann, 1991). An important challenge in curriculum making processes is to gain the acceptance for the new law and its content from practitioners, the public, politicians, or administrative bodies. In addition, the law has to cover a highly diversified landscape of schools and schooling with varying local characteristics and needs, different school types, and different age groups. A historical analysis of curriculum making processes in Prussia (Hopmann, 1991) revealed three basic features that reveal the close connection between a curriculum and the society in which it is enacted. First, the process of curriculum making and enactment has become highly differentiated. As a consequence of the formation of ever more differentiated structures in administration, curriculum work has become subject in a number of institutions, authorities, and administration bodies. These compartments provide a common ground for expertise in the multifaceted issues in curriculum making and enacting, while the people at the same time are able to hide between a corporate responsibility, where no one could be made responsible for the whole (Hopmann, 1991; Westbury, 2008). In so doing, the administration of a nation state ensures that the complex project of developing one national curriculum is processed on a formal level by organizing decision making processes. At the same time, compartmentalization contributes to the consolidation of a nation state’s administration body, because it helps to make reform and decision making processes more efficient. Second, curricula are by definition

instruments of “administrative supervision” (Westbury, 2008, p. 52), and therefore separated from instruction planning at the classroom level. This means that the teachers as executives of the curriculum gain freedom in operating and enacting the framework given in the curriculum and are free to choose between content matter and methods. When choosing content matter and making decision on methods, teachers draw on the curriculum in order to legitimize their choices and decisions. The feature of licensing therefore also allows for a division of responsibilities that diversifies the burden in case of failure. At the same time, it lays ground for a powerful discipline that will be presented in the next section: the discipline of *Didaktik*. The freedom of methods and its separation from the curriculum is thus a key concept for understanding how curriculum, *Didaktik* and *Bildung* are connected to each other. Third, curriculum making needs to take the demands and experience from various groups of people into consideration. By the segmentation of the levels of discourse in curriculum reform, different parts of the society that are involved in the reform matter, get an arena where they can be included into the process. The process of negotiating which content matter is supposed to be included in the curriculum becomes part of a public and partly transparent deliberation where practitioners and other people involved can bring forward arguments, take position, contribute aspects and perspectives to the discussion and give precise reasons for what they are demanding and claiming. This happens both in formally organized conferences and meetings between practitioners, public officials, and politicians and in informal ways by for example participating in media discourse. The three features of compartmentalization, licensing, and segmentation balance and steer the different interests in curricula as a governing tool. On the one hand, they assure not only that professional expertise is laying the ground for a curriculum, but also develop structures for how to organize this expertise (compartmentalization). The functioning of societies relies heavily on professional expertise as a bundle of knowledge and expertise that exaggerates the stock of knowledge that an individual person can have. The licensing feature as the core ground for the teachers’ professional practice allows teachers to justify their work toward the society on the basis of the curriculum. The segmentation of discourse assures that all people who have an interest in the future generation’s education can participate and share thoughts (Hopmann, 1991). Curricula from this perspective are not an instruction defined by one authority, but a matter that takes shape through societal deliberations and negotiations between different parts of the society.

The core element of a curriculum is of course the content matter that is listed and described in the document and that is supposed to be taught by the teachers. Content matter is Hopmann (2007) presented along three dimensions that also evolved one after another in the course of history. The first dimension, order, is about the structure and concepts of knowledge that is imparted to each subject and each content matter. Through curricula, content matter is on the one hand set into relation to a bigger picture, a superior classification of which the content is a part. On the other hand, content matter can be broken down into smaller aspects that are part of the content’s structure and that in fact characterize it. The second dimension deals with the sequence of subject matter, and the question how subject matter can be presented in a way that the students can follow and understand it. The sequence can reveal an order according to the difficulty of content matter, it can follow a chronological order, a thematic order, it can reach from the near to the far, and follow the different development levels of children. The third dimension, choice, is owed to the circumstance that a curriculum can never cover all knowledge that is available for humankind. It therefore can only present a choice of content matter, that either is exemplary, considered to be of high relevance, teachable, or which differs in other respects from what is decided to not be included in the curriculum. These three dimensions provide not only the basic framework for the formal document of curricula, but also of the teachers’ planning process, where they arrange content matter according to the needs of the students (Hopmann, 1991).

Historically regarded, the process of developing curricula was dedicated to the search for a universal, God given order of things, into which humankind should gain insight. However, in the course of time, the universal approach became increasingly reduced by following the above mentioned dimensions. After attempts to create universal pictures of knowledge, the sequence of content matter became important, followed by the necessity to choose specific content from the vast variety of knowledge of humankind (Hopmann, 2007). It was not before national states were founded that curricula have taken the shape we are familiar with today. The desire to develop a national identity and membership/loyalty among the nation states’ citizens, and especially among their future generation, has led the way for curricula that chose content matter shaped and in line with a national narrative (Tröhler, 2016). In contrast to the idea of the “*enkyklia paidea*” in ancient Greece, the aim was no longer to cover the whole available knowledge to humankind, but to define a nationally relevant choice of knowledge that can build the fundament of a society. The complex process of curriculum making reveals how close curricula are related and dependent on the society in which they are supposed to be implemented. Curricula in our times are developed within a specific society, and for a specific society, and therefore both are mutually dependent on each other.

Didaktik

Didaktik has again its origin in German theories and goes back to Ancient Greek terms. “*Didaskein*” means to teach and to show or perform something and has been developed to the “art of teaching.” It is the “pedagogy of teaching” (Oettingen, 2016) and provides, as a science of teaching, the knowledge teachers need for being able to teach (Oettingen, 2016). One can differentiate between subject matter didactics which deals with teaching of content matter of a specific subject and general didactics which is about general phenomena, premises and characteristics and of teaching.

As in case of the term *Lehrplan*, the term *Didaktik* is difficult to translate into English. While the English term “didactics” rather refers to methods of instruction and the science of teaching, the German term rather opens for the reflection on the question how content matter can be made meaningful to a group of students by a teacher. The important difference between these two

understandings lies in the concept of *Bildung* that is inherent to the German term *Didaktik* and that will be presented in the next section of the article.

Curricula in terms of *Lehrpläne* set essential conditions for teaching. They provide a legal and publicly accepted framework of content matter and give the teachers freedom in what content they choose and how they enact it in the classroom. This freedom allows teachers to develop their approaches in adaptation to their specific classroom at hand, with their students' specific needs and based on their professional experience and knowledge. The cornerstones under which this freedom develops become visible in a schematic representation of models of didactics, the didactic triangle (Künzli, 1998). It visualizes the relations between the general elements of teaching, i.e. the teacher, the student, and the content matter, which are indispensable conditions for institutionalized learning and define the core of didactics. Different *Didaktik* approaches emphasize specific relations within the triangle and put different amounts of weight to the role of each component. However, learning only unfolds within the relations between the three components teacher, student, and content. In search of the common core of *Didaktik*, Hopmann defines three distinctive corner stones of *Didaktik* that at the same time visualize its historical development in line with curricula: didactics as a matter of order, sequence, and choice (Hopmann, 2007). In terms of order, didactics deals with providing the students with a structured preparation of a certain content matter that helps the students with gaining insight into its inner structure and the higher order of which the content matter is a part. Simultaneously, any matter at hand features a specific logic that implies different steps in the teaching process. By drawing on their professional expertise and experience, teachers can thus prepare meaningful steps and tasks for the teaching of the same content. The matter of sequence relies mostly on the work of Johann Amos Comenius and his "Didactica Magna" where he elaborates not only on the structure of the content as a realm of teaching, but also on the student's relation and their presuppositions. Therefore, Comenius suggests to start teaching from the (student's) near and proceed to the far, from the simple to the complex, or from the more obvious and known to the more abstract and unknown. The third corner stone is choice, which refers to the necessity to choose between a variety of content depending on the appropriateness and the specific needs of the students at hand. The enormous wealth of knowledge that is available to humankind requires thoughtful choice of what is ought and worth being taught to tomorrow's generation. *Didaktik* unfolds here between a political framework in terms of the curriculum and the teachers' local practice: the curriculum serves as a basis for the legitimation of choosing (or not choosing) a specific content, while the actual enactment of the content underlies the teachers' professional expertise and experience. By finishing their education in teaching, teachers receive, in Hopmann's terms, a license for transforming and enacting content matter as provided by curricula according to best pedagogical practice (Hopmann, 1991). The three cornerstones describe the art of teaching as a way of restraining the students' exposure to an overwhelming flow of knowledge and content: teachers need to prepare content according to its structure, develop a sequence for the presentation of different steps, and choose specific content matter from the wealth of available knowledge. As argued by Herbart, the art of teaching mainly builds on the teachers' experience in preparing content matter according to the conditions and needs of their class at hand, and reasonate about it and legitimate it by drawing on the curriculum. The teachers' capability to realize pedagogical needs and necessities and to react in a decent way by making new decisions, is the actual art of teaching that is based on experience and ethics. By drawing on Herbart's concept of tact, Max van Manen describes the teachers' spontaneous pedagogical reactions as the foundation of teaching (Van Manen, 2016, 1986).

Bildung

The term *Bildung* is to be understood on the backdrop of a Jewish-Christ tradition of thinking. The "deo imagi" (picture of God) denotes the symbolical relation between God and the human being and points to the difference between the picture of the human being as it is, and the picture that she or he is supposed to become. This difference is expressed as a longing for self-improvement with the ideal picture of God in mind (Ehrenspeck, 2006). The word "picture" means *Bild* in German, which does not only mean the picture as such but the verb *bilden* also means the process of "forming." Also in its secularized meaning, the idea of *Bildung* refers to a mutual relation between the human being and the world, with a forming and changing effect for the human being, and, eventually, also for the world. In the context of schooling, the dialectic interplay between the learning human being and the content matter representing the world is extended with a social dimension. Not only the teachers as mediating persons participate in the learning, but also other students share the learning process and turn it into a common effort to develop a common understanding of the world. Learning is, from this perspective, not about accumulating knowledge in a material sense, but about making meaning of a specific content that represents a canon of knowledge to be learned. It presupposes a theoretical distinction between content matter and meaning which represents at the same time the intersection between curricula, *Didaktik*, and *Bildung*. While content matter is the knowledge defined in the curricula, the didactical question is how content can be made meaningful to the students. The meaning-making process is a unique, situated encounter of the student's previous, biographically determined stock of experience with the content matter under those didactical conditions that the teacher creates (Hörmann, 2011, 2015). *Bildung* therefore emerges as an individual meeting in which students activate "memories of prior personal experiences" (Menck, 2006, p. 116) and, in so doing, gain a "picture" in their imagination that represents the meaning of the content taught by the teacher. The fact, however, that learning in school is embedded in a social setting, makes the process of meaning making interactive. By communicating with their classmates and the teacher, students put forward different intuitive or immediate perceptions (Willbergh, 2008) and share a common, vivid presence in which they become participants of a common effort to understand, define, and categorize the world. The teacher navigates through this process and doses the extent of guidance according to the students' needs and becomes a participant in the common effort of understanding and exploring the issue at hand. By restraining teaching (Hopmann, 2007), teachers

create conditions under which both individual growth and social exploration and deliberation can become possible. The main purpose of this process is to develop educative substance or meaning which can be opened up by any content, while any given matter can represent many different meanings (Hopmann, 2007, p. 116). This relation allows the teacher to take into account the students' various backgrounds and different stocks of experience within the endeavor of making content matter meaningful to them. Content matter in a narrow sense and the academic disciplines in the form of school subjects in a wider sense denote/are of a rather exemplary character that serve as a framework for the students' exercises to understand concepts, structures, and categories of the world (Künzli, 1981). According to Klafki, one main purpose in lesson planning and teaching in general is to reflect on the meaning of the specific content for the presence and the future. This points to the school's mandate to prepare students for their future life as members of a democratic and highly complex community that requires citizens who are not only able to read and write, but who also can communicate with each other, share a common presence, and actively participate and engage in society (Klafki, 1967, 2007).

Especially by drawing on Humboldt's theory on *Bildung*, scholars and practitioners often promote *Bildung* as a transformation with the purpose of self-improvement by dealing with content matter from the classical arts and languages and focusing on esthetics. From a social historical perspective, *Bildung* has been a bourgeois ideology for promoting the interests of a privileged and aspiring social class in the 19th century (Horlacher, 2015). Despite of a variety of theories and practices around the idea of *Bildung* and different readings such as, for instance, by the *Frankfurter Schule* (Horlacher, 2015), modern schools have been strikingly characterized and formed by a bourgeois understanding and attitude toward learning and knowledge, not least because both policy makers and teachers often originate from these backgrounds. This leads to the situation that students from other backgrounds than the typically bourgeois educated family suffer from a mismatch between the school's and teachers' expectations and their biographically marked resources. Nevertheless, scholars in classical didactics emphasize a comprehensive understanding of *Bildung* which is not confined to specific sets of content, but regard any content matter as an exemplary representation of the world that can turned into meaningful learning experiences for all students (Klafki, 1967). Education is in this framework the nurturing of a natural development process that is inherent to each human being ("The human being carries the sufficient reason for its development in itself from the beginning of life until the point of its completion" origin: "*Der Mensch ist ein Wesen, welches den hinreichenden Grund seiner Entwicklung vom Anfang des Lebens an bis zum Punkt der Vollendung in sich trägt*" (Schleiermacher, 1826), own translation).

Different readings and theories on *Bildung* reveal a diverse picture of the phenomenon and turn it into a concept that is drawn on from many different angles and parties (Horlacher, 2015). In recent times, it is often used as a counter concept to education in the framework of competences and performance improvement. At the same time, proponents from standardized and competence oriented teaching proclaim the literacy concept to be a renewed version of the idea of *Bildung*. In the German language, *Bildung* can mean any kind of education and it is not confined to a specific concept. However, by drawing on a didactical framework, this article presented *Bildung* in relation to the didactic premises and thinking.

Recent developments

In the course of internationalization and globalization, many nation states have implemented competence-based curricula and oriented their education policies toward learning outcomes in terms of standardized testing. Curriculum making and education policy making have become both international and national projects which has led to a situation in which policies are oriented toward globally disseminated ideas, while these ideas simultaneously are reshaped and renegotiated on a national level (Sivesind and Wahlström, 2016; Steiner-Khamsi, 2012). Competence based curricula, for instance, have become a common reference point in education reforms in many countries all over the world, national governments, however, responded in fact differently to the common idea and reshaped and renegotiated it by drawing on their traditions and cultures (Karseth and Sivesind, 2010; Sivesind et al., 2016). For instance, in comparison to Norway, Finland's curricula balance both content oriented with a learning outcome oriented descriptions in the syllabi, whereas Norwegian curricula are based on a learning outcomes approach (Mølsted and Karseth, 2016). Anderson-Levitt also points to varying and inconsistent implementations of competence approaches in curricula in different countries with regard to the underlying theoretical premises or different foci on the students' individualized progress vs. integrative, project-based approaches (Anderson-Levitt, 2017).

The current trend of standardized testing and competence based teaching itself can be regarded as an adoption of elements from two long-standing traditions; the German *Didaktik* tradition on the one hand, and the Anglo-American curriculum tradition on the other hand. The test culture originating from the Anglo-American tradition combined with state based curricular formats have become a rapidly expanding movement, causing fundamental changes on the policy and the practical level (Hopmann, 2015). From a didactical perspective, competences connect content matter with a specific meaning and therefore suspend the distinction between the two aspects under which *Didaktik* unfolds (Hopmann, 2007). Within the competence paradigm, the focus of teaching lies on the students' competence development, whereas teaching in the tradition of *Bildung* rather deals with opening up content matter for the students in a way that it becomes meaningful to them. A vague concept like this is criticized because it sets mastery in a relative context and appears too subjective. Competence concepts however promise objective proofs for the successful mastery of knowledge by formulating cognitive goals and testing the students' performance with standardized tests (Köller, 2008). The licen-siation for teachers to enact content matter appropriate to their professional pedagogical standards is subject of change in a competence framework, because content matter becomes applied knowledge where the meaning is prescribed (Hopmann, 2007). Teaching under these terms means to "facilitate learning" (Biesta, 2013) by working with the students on their mastery of specific

applications of knowledge with a focus on each individual's progress (Masschelein and Simons, 2013). Since each individual's progress is to the fore, the meaning of the social dimension of learning and deliberating together in the classroom diminishes. This means that the focus of schooling lies on its qualifying function while its socializing and subjectivization functions become subordinated (Biesta, 2009). Bildung is redefined as the successful mastery of specific, applied knowledge represented by the concept of literacy that promises to provide students with the knowledge required in societies of the future (OECD, 2005).

Concluding remarks

This article has presented core concepts of education that originate from German discourse and at the same time have become subject of and involved in international renegotiations and processes of exchange. Curricula, *Didaktik*, and *Bildung* are cornerstones in public education in schools in modern nation states that have historically grown out of the need for institutions that secure the future generation's education and the continuance of the nation states. Recent policies are oriented toward international trends and global ideas and have led to profound changes of national curricula which are now based on competences. Besides from an international influence, an increased influence from the private market on educational practice lead to the situation that national states play a "denationalized role" in policy making where the role of the nation state tends to be transformed from an "enabling" to an "influencing-liberal" state (Sundberg and Wahlström, 2012; Wahlström, 2014). In the further course, the change in the conceptualization of curricula has empirical consequences for the enactment of teaching and the idea of the aim and purpose of schooling. These changes have been investigated extensively and critiques mostly refer to the narrow understanding of education in the competence and testing framework and the pressure that is put on students, teachers, and parents (for example Biesta, 2009; Hopmann, 2007, 2008; McGill-Franzen and Allington, 1993; Otto and Schrödter, 2010; Willbergh, 2015). An important area of future research however could be the way how old and new elements in curriculum and teaching are combined with each other and how accountability tools can be integrated into a genuine pedagogical understanding of schooling that balances the schools' functions and mandates with the purpose of opening the students future possibilities for an autonomous, good and succeeding life (Bachmann et al., 2021; Geppert, 2014).

Trends and issues on the boundaries where curriculum implementation and curriculum making merge	346

In the early 1900s, John Dewey detected a perplexing phenomenon among American teachers. Some, he noted, “[knew] how to teach, but they [were] not students of teaching” (Dewey, 1904, p. 215). They were not able to “... act on their own initiative, [even when they were] expected to do so.” “Tak[ing] on situation[s] for themselves” rather than following a “set method or scheme” seemed unlikely (Dewey, 1904, pp. 27–28). To Dewey,

a willingness [prevailed within] the teaching corps to accept without inquiry or criticism any method or device, which seem[ed] to promise good results... [and] teachers... [would] flock to those persons who give them clear-cut and definite instructions as to how to teach this or that (Dewey, 1904, p. 152).

Joseph Schwab, who became a professor the year Dewey's *Experience and Education* (Dewey, 1938) was released, similarly underscored the need for teachers who are able to make minded curriculum decisions. In Schwab's view, these teachers would be “agent[s] of education, not [simply] of subject matter” (Schwab, 1954/1978, p. 128)—with the delivery of subject matter being policymakers' main concern. For Schwab, the only plausible road to educational improvement comes through teachers who have the ability to reflect on their practices alone and together:

... only as the teacher uses the classroom as the occasion and the means to reflect upon education as a whole (ends as well as means), as the laboratory in which to translate reflections into actions and thus to test reflections, actions, and outcomes, against many criteria is he [sic] a good ... teacher (Schwab, 1959/1978, pp. 182–183).

To the observations of Dewey and Schwab, the insights of Philip Jackson will be added. Jackson was among the first to conduct research alongside flesh-and-blood teachers in schools. In *Life in classrooms*, he famously reported that teachers' work does not follow the straightforward trajectory of a bullet, which is what legislative bodies expect to happen. Instead, teachers' work zigs and zags, resembling the “flight of a butterfly” (Jackson, 1968, p. 67). Jackson's groundbreaking research, like that of Dewey and Schwab, draws attention to important conditions and phenomena that do not “scream out at you” in school milieus but “reveal through language [their] presence and meaning” (Eisner, 2007, p. 156). Written in the research tradition of Dewey, Schwab and Jackson, this chapter, building on the scholarship of Connelly and Clandinin (Connelly and Clandinin, 1988; Clandinin and Connelly, 1992, 1995), focuses on what has unfurled on the boundaries over the past 30 years as teachers have negotiated the mandated curriculum in tension with curriculum as it becomes lived. This work, which is culled from my research program, begins with an overarching literature review and a brief discussion of narrative inquiry. Serial interpretation, this chapter's primary research tool, is paid special attention. Five examples of bumping up places between teachers' implementing required curriculum and teachers'

animating required curriculum come next. This chapter ends with a discussion of the themes and trends evident in the exemplars and offers suggestions as to where the field of education might go from here, given the current state of lived curriculum, which alternately is called experienced curriculum (Connelly and Clandinin, 1988).

Literature review

Several important concepts underpin this synopsis of lived curriculum as it appeared in my research program. Concepts setting the backdrop for this three-decade review include (1) boundaries, (2) curriculum, (3) teacher knowledge/knowledge of teaching, (4) images and metaphors of teaching, (5) teacher community, and (6) teacher identity. Brief summaries of each appear next.

Boundaries

A boundary is an imaginary place where one field brushes against an “intellectual territory of another way of thinking” (Clandinin and Connelly, 2000, p. 21). The latter territory may suggest other ways of doing and being than those advocated by the initial field (Boyer, 1990). Not only do these “bumping up places” appear when research studies are enacted, they also happen in flesh-and-blood settings. This is because people’s lives—those who do research and those who are researched—“flow across the boundaries” (Clandinin and Connelly, 2000, p. 115). Hence, all research is “preceded and surrounded by other texts, some of which are evoked [and] some of [which are] not” (Lather, 1991, p. 9). Freema Elbaz-Luwisch (2005), for instance, used the terms, “the story before the story” (p. 358) and “coda” (p. 377), to capture the complexities of the contextual backdrop of her scholarship before and after her study. In this chapter, I explore “edges” in my work and “examine [more fully] the context in which ... [my] research was carried out” (Elbaz-Luwisch, 1997, p. 79).

Curriculum

Curriculum can be defined as a “course of study” (a document) or “a course of life” (Clandinin and Connelly, 1992, p. 393). When curriculum is not a manual (Westbury, 2000) or a cookbook (Oyoo, 2013), but something organic, rigorous and relatable, vital connections can be made to curriculum as a lived experience and the commonplaces of curriculum (Schwab, 1962; Craig and Ross, 2008). The curriculum commonplaces are near-unanimous considerations (Goodson, 2007) to which educators attend. Teacher, learner, subject matter and milieu are equally present in the making of curriculum. Combined, they bound “the curricular” (Connelly and Clandinin, 1988, p. 84). Curriculum making, in Schwab’s view, “res[ts] not on ideal or abstract representation, but on the real thing, on the concrete case, in all its completeness and with all its differences from other concrete cases ...” (Schwab, 1969, p. 11). Lived curriculum focuses on “practice and action, not [others’] theor[ies] and meaning[s]...” (Connelly and Xu, in press, p. 8). It places “people in front of ideas, experience in front of products and judgment in front of ... instructional scripts” (Hlebowitsh, 2012, p. 10). The real thing—the concrete case—is what Ted Aoki (1989/1990) termed the “full-life of curriculum” and what Jean Clandinin and Michael Connelly called the lived curriculum. Within particular classroom spaces, “teachers and students live out a curriculum ... An account of teachers’ and students’ lives over time is the curriculum, although intentionality, objectives [abstractions], and curriculum materials do play a part ...” (Clandinin and Connelly, 1992, p. 365). Hence, when Schwab declared that “a curriculum ought to be known by the persons it produces, as well as other signs and standards” (Schwab, 1983, p. 247), he meant that curriculum, viewed through a “curriculum of lives” (Clandinin and Connelly, 1992) lens, should be judged by how people’s lives are lived, in addition to how curriculum mandates have been satisfied. Distilled to its essence, curriculum should influence the kinds of human beings people become, given that democratic community is foundational to human flourishing as Dewey, Schwab, Jackson, Eisner, Connelly, Clandinin and others (i.e., Greene, 1995) have stressed.

Teacher knowledge & knowledge-for-teaching

Because teachers are the “fountainheads of the curriculum decision” (Schwab, 1983, p. 24), policymakers and researchers approach teachers’ primacy in the teaching-learning process in different ways. Other than teacher proofing (Tanner and Tanner, 1990) where teachers play no role at all, two knower and known relationships exist (Dewey and Bentley, 1949; Fenstermacher, 1994): (1) the knowledge-for-teaching approach, and (2) the teacher knowledge approach.

The knowledge-for-teaching perspective upholds the view that a body of knowledge exists that every teacher should know and do. For proponents of knowledge-for-teaching, such knowledge is determined by others and widely circulated “to build knowledge structures that are said to accumulate” (Eisner, 1997, p. 7). For them, educational improvement means mandating more or better knowledge for teachers to implement. In this view, teachers install others’ plans and the knowledge they deem most important (Clandinin and Connelly, 1992; Craig and Ross, 2008). In this scenario, teachers are “hand-servants” (Hansen, 2011) through whom others’ declarative knowledge passes. In these situations, curriculum is fixed like “a package ... delivered ... by bulk postal mailing” (Rosiek and Clandinin, 2016, p. 296).

Standing in juxtaposition to this view is the teacher knowledge stance, which understands teaching in teachers’ own terms. In this view, teacher knowledge is produced by teachers in the midst of, and as a response to, lived curriculum practices. At the heart of this version of teacher knowledge sits experience. This is because “knowledge arise[s] from experience and return[s] to experience for

validation" (Clandinin and Rosiek, 2007, p. 39). Even knowledge-for-teaching becomes sifted through the lens of experience in the teacher knowledge approach. There is no other way for policy or research imperatives to enter teachers' minds than through their experiences and no other way for them to enter teachers' bodies than through teachers' minds and embodied actions (Craig et al., 2018). Fenstermacher (1994), in his groundbreaking review of practical teacher knowledge programs, named three leading schools of thought: Russell and Munby (1991), following the Schön (1983) line; Connelly and Clandinin (Clandinin, 1986; Connelly and Clandinin, 1985), who with Elbaz-Luwisch (1983, 1991), built on Schwab's (1969) practical tradition; and Cochran-Smith and Lytle (1990, 1993) reflecting the teacher-as-researcher strand (Stenhouse, 1976). While somewhat different, all these research thrusts capture teachers personally and professionally coming to know their practices as minded human beings (Dewey, 1904, 1908/1981, 1938).

Following the Connelly-Clandinin line of research, my body of lived curriculum scholarship views teacher knowledge as "a narrative construct which references the totality of a teacher's personal practical knowledge gained from formal and informal educational experiences" (Xu and Connelly, 2009, p. 221). To Connelly and Clandinin (1988), personal practical knowledge is "... in the person's present mind and body, and in the person's future plans and actions ... It is seen and found in [teachers'] practices" (p. 25). Distilled to its essence, teachers' practices instantiate their personal practical knowledge, given that teachers are curriculum makers (Clandinin and Connelly, 1992; Craig and Ross, 2008), not merely implementers of others' knowledge injections.

Images and metaphors of teaching

Images

The widespread image of teachers-as-curriculum-implementers approaches teachers as agents of the state, charged with institutionalizing its edicts. In this view, shifts in teachers' practices happen because teachers are bound to the laws policymakers establish. In this scenario, the teacher is a "technician, consumer, receiver, transmitter, and implementer of other people's knowledge" (Cochran-Smith and Lytle, 1999, p. 16). This view of teachers being positioned in an educational conduit (Clandinin and Connelly, 1995; Craig, 2002), delivering curriculum like "passing on a bag of goods" (Hansen, 2011, p. 1), has spread internationally because of theory's long-standing estrangement from practice (Schwab, 1969). This hierarchical approach to change is highly problematic because, as emphasized earlier, teachers' practices embody their personal practical knowledge (Craig et al., 2018). This is far more complex and expansive than compliant teaching, which forestalls teachers' voices and agency (Rodgers, 2020b), returning us to Dewey's concerns about automaton teaching at the turn of the century.

Unfortunately, the dominant paradigm ignores an alternate image of teaching, one that recognizes teachers as active agents (Schwab, 1954/1978) and the mindedness Dewey (1908/1981) afforded them. In this view, teachers "*must* be involved in debate, deliberation, and decision about what and how to teach" (Schwab, 1983, p. 245, italics in original). The teacher-as-curriculum-maker construct underscores the preeminence of the teacher in organizing, planning, and orchestrating classroom interactions because only the teacher is positioned at the interstices of the curricular exchange and meets students in moment-to-moment ways. Thus, curriculum is what happens—what becomes animated—in the breath-to-breath instants when teaching and learning fuse. Distilled to the essence, experiential knowledge—practical knowledge—cannot be tested, packaged and delivered because human beings (teachers, students) are inseparable from the body of knowledge that exists (i.e., Dewey and Bentley, 1949; Fenstermacher, 1994) and essential to the curriculum making act (Schwab, 1983). Cut to the quick, the teacher is "the most responsive creator of curriculum" because he/she "negotiates the formal planned curriculum of governments and publishers within his/her practice, alongside the lives of learners" (Murphy and Pushor, 2010, p. 658). Consequently, in the teacher-as-curriculum-maker image, attention turns from written plans, authorized textbooks and government mandates (Clandinin and Connelly, 1992; Connelly and Clandinin, 1988), which typically privilege subject matter and destine teacher to dispensers of knowledge roles, to curriculum as it is lived within the context of people's lives (Downey and Clandinin, 2010). The latter image is an amalgam of Schwab's four curriculum commonplaces (teacher, learner, subject matter, and milieu) with the teacher serving as the intermediary. What becomes animated are the most important aspects of teacher knowledge, which are "ephemeral, passionate, shadowy and significant ... for the most part ... reflect [live of] teachers' lives" (Connelly and Clandinin, 2004, p. 42).

Metaphors

Like all other human beings, teachers employ metaphors to convey their pedagogical understandings to themselves and to carry across ("metepherein"—the original Greek word) their meaning to others. Using metaphors, they capture and communicate knowing of one phenomenon through the aperture of another phenomenon. In narrative research, lived metaphors that drive and reflect human experience are powerful tools for understanding teachers' knowledge and practices. Distinctions, however, exist between the kinds of metaphors that teachers use: (1) novel metaphors and stock metaphors, and (2) emergent and ascribed metaphors. Novel metaphors are imaginative and possess generative power (Schön, 1993). Such metaphors are compact, express the inexpressible and vividly illuminative. Conversely, stock metaphors risk over-use and "sedimentation" (Brown, 1976, p. 175). In short, stock metaphors are trivial and shape practice in non-illuminative ways. Emergent and ascribed represent two of metaphor's other distinctions. Emergent metaphors (Breault, 2006) are intuitively held and naturally surface in novel or stock ways in a teacher's language and unfolding practice. By way of contrast, ascribed metaphors (Breault, 2006) are novel or stock metaphors that researchers intentionally adopt to describe a phenomenon they have identified or teachers' perceived experiences of teaching (Nieto, 2003). Further to this, teachers can individually choose metaphors to live by (Lakoff and Johnson, 1980) as part of their professional growth (Wagenheim et al., 2009). Whether identified by a researcher or by a teacher, ascribed metaphors are choices

made from a vast range of alternatives. Once a metaphor is chosen, the teacher's practice is molded and shaped by the researcher and/or the teacher to fit within the boundaries of the metaphor. The metaphor then becomes the interpretative lens through which the teacher's pedagogical practice is bounded.

Teacher community

Many researchers have offered theories of teacher community (Grossman et al., 2001; Thomas et al. (1998); Wineberg and Grossman, 1998). Others such as Lieberman (1992) have examined the development of the scholarly community and networks (Lieberman, 2000) as reflective forums. Craig (1995b, 2007, Curtis et al., 2013; Craig et al., 2020a,b) and Craig and Olson (2002) further conceptualized the development of teachers' narrative authority in knowledge communities. For them, knowledge communities are "safe, storytelling place where educators narrate the rawness of their experiences, negotiate meaning for such experiences, and authorize their own and others interpretations of situation" (Craig and Olson, 2002, p. 116) as "legitimate tellings" (Mishler, 1986). Teachers' knowledge communities take shape around "commonplaces of experience" (Lane, 1988, p. 188) rather than bureaucratic and hierarchical relationships that determine who knows, what should be known, and what constitutes "good teaching" and "good schools." A further notion of teacher community, which frequently brushes up against knowledge communities, is the idea of professional learning communities (i.e., DuFour, 2003; DuFour and Eaker, 2009), a conceptualization introduced through the organizational literature. In this view of community, administrators preordain the communities in which teachers will interact and determine the topics they will discuss, which is antithetical to what is known about the knowledge communities teachers naturally form.

Teacher identity

Teachers' identities are their "stories to live by" (Connelly and Clandinin, 1999). Their identities are "composed and improvised as [they] live [their] lives embodying knowledge and engaging contexts" (Clandinin and Connelly, 1999, p. 4). Teachers' stories to live by affect "the making sense and reinterpretation of [their] ... values and experiences" (Flores and Day, 2006, p. 220). In addition, emotion is intimately involved in "how ... [their] selves come to be constituted" (Zembylas, 2005, p. 27). In short, teacher identity is the "product of shared story telling" (Sfard and Prusak, 2005, p. 10) and is manifested through teacher voice and agency (Rodgers, 2020b).

Narrative inquiry

Narrative inquiry is the "experiential study of experience" (Xu and Connelly, 2010, p. 354). In this research approach, narrative serves as both the phenomenon of inquiry and the method of investigation (Clandinin and Connelly, 2000; Connelly and Clandinin, 1990). Story is "the portal through which a person enters the world" (Connelly and Clandinin, 2006, p. 477) and a "portal to experience" (Xu and Connelly, 2010, p. 352). It is "not so much a structured answer to a question or a way for accounting for actions and events, as it is a gateway ... for narrative inquiry into meaning and significance" (Xu and Connelly, 2010, p. 356).

Relational in form, narrative inquiry has three commonplaces: temporality, sociality and place/situation. The term, commonplace, connects it to Schwab's (1969) "practical, a language for curriculum" whereas temporality, sociality and place/situation trace narrative inquiry's origins to Dewey's (1938) philosophy of experience. Thus, for a narrative inquiry to be field-based (Xu and Connelly, 2010), all three nodes must be present and interacting in the investigation.

Several field texts provide the narrative grist that morph into research texts. These include personal interviews, focus groups, and material objects of reflection. In addition, journal entries can be written and receive response. To this, participant observation notes from classroom observations, faculty meetings and department meetings, and lesson and unit plan documents can be added. Furthermore, teaching and meeting interactions can be videotaped and even digital narrative inquiries (Craig, 2013) can be prepared in advance of writing and publishing final research texts.

Broadening, burrowing and storying and restorying (Connelly and Clandinin, 1990) are the three main analytical tools that I used to gather the original narrative material having to do with lived curriculum. A fourth narrative inquiry tool, serial interpretation (Schwab, 1954/1978), will now be further elaborated. Serial interpretation is the tool I used to prepare this encyclopedia chapter. It allows one to identify "encompassing idea[s]" that traverse multiple studies. It involves "talking across" (Stone, 1988, p. 2) research projects—even countries—as I will do in this chapter. Serial interpretation adds heft and power to single case studies by bringing them together around a meta-topic, which is lived curriculum where this chapter is concerned.

Lived curriculum making stories

In this section, five stories representing five educators' experiences will be presented. Combined, the exemplars convey critically important lessons gleaned from my 30 years of conducting research in public schools in western Canada and the mid-southern

Fig. 1 Timeline of narrative accounts (1990–2020).

US. The first exemplar comes from Canada whereas the four remaining ones occurred in the US. I have included time frames for the specific stories so readers can situate their personal and professional experiences alongside the narrative accounts I share (Fig. 1).

Stories of teachers/teacher stories: Benita Dalton 1990–1996

My early research experiences in Canadian classrooms involved research participant, Benita Dalton, with whom I conducted both my doctoral and post-doctoral research studies. I followed Benita from her preservice teacher education program (Craig, 1995a, 1995b, 1995c), to her practicum experiences, and finally into her beginning teaching positions at three different schools in Western Canada. Benita learned how to team teach in her teacher preparation program and during her extended practicum experiences in the field (Craig, 1998) when she was placed on a six-member teaching team. However, when she entered her first school setting after graduation, her teaching partner was not enamored with co-teaching and physically and metaphorically shut the folding wall between their classrooms. This ended all possibilities of them team teaching from that moment onward. The situation taught me that team teaching partnerships must appeal to both partners. Both teachers—regardless of prevailing philosophies—must be committed to team instruction. At the most basic level, a shared agenda—a commonplace of experience (Lane, 1988)—must exist in order for teachers to overcome personal boundaries and join together in shared instruction.

At her second school, Benita experienced a different team teaching arrangement when she team-taught with two teacher peers. What the three teachers did this time around was to pretend to teach collaboratively without making too much of a time investment. In reality, they lived a cover story (Clandinin and Connelly, 1995; Olson and Craig, 2005). In actuality, they taught in collusion alongside one another, intentionally concealing the subterranean nature of their partnership (Craig, 1998). Benita and her co-partners pseudo-team taught because the school district and the school principal wanted them to co-instruct their multi-aged grades of students. However, the children's parents were adamantly opposed to the campus's administrative and pedagogical approach. The projection of a visible team teaching image became the way the teachers managed tensions they experienced at the boundaries between and among the school, its district and the community it served. This allowed them to persevere without being implicated in the brouhaha over who had the most power in setting the campus's agenda.

Finally, when Benita moved to her third school, she was placed with a new teaching partner and became part of a six-member, Grade 3 team where everyone—the principal, the parents, the teachers and the community—favored team teaching practices. Because Benita shared her developing personal practical knowledge (Clandinin, 1985) with me and allowed me to conduct research alongside her in her vastly different school settings, I learned—in an up-close way—that the contexts of teaching greatly shape what teachers like Benita can do and be, regardless of what they *know*. In short, through conducting research with Benita Dalton, I learned that team teaching is not simply an individual decision because it has to do with everyone else and everything else, most especially teachers' abilities to cross classroom boundaries, grade level boundaries and age level boundaries as well as parental boundaries, school district boundaries and philosophical and political boundaries. Reduced to the essence, teachers' knowing and doing is anchored in place. *Teachers are only able to do what their contexts allow them to do, in spite of their prior knowing and doing in other school milieus as this stories of teachers/teacher stories juxtaposition vividly shows through the experiences of one induction year teacher working in three consecutive school sites.*

Stories of school/school stories: Henry Richards 1998–2004

This second example revolves around the dragon in school backyards, a small story hard to forget (Davis, 2003). The school story, whose origin is folklore, is one told by Henry Richards, a former principal of Eagle High School. His campus, which expanded from 2200 to over 3000 students during the time I conducted research there, "changed almost overnight." (Craig, 2004, p. 1236). It initially was a nationally named Blue Ribbon School with mostly white students. It then became a sports powerhouse serving mostly Black and Latinx youth. Henry told the plotline of his changing school milieu to anyone who would listen: teachers, students, parents, researchers, other principals and members of a \$60 million dollar reform movement of which his campus was a part. The gist of Henry's tale went like this: "When you work in a school and there is a dragon in your school backyard, you

had better prepare for the dragon The dragon, of course, is the accountability system ...” (Craig, 2004, p. 1230). The accountability dragon of which Henry spoke had to do with the high stakes tests administered to students annually. These tests affected students’ life chances as well as the bonuses awarded teachers and principals. These exams became the measuring sticks through which the school district judged its principals, teachers and schools and through which the state, in turn, judged its school districts. Everything was about “measured experience”; very little, on the surface at least, was concerned about “lived experience” (Hlebowitsh, 2012, p. 2).

While digging deeply into Henry’s telling, a second dragon image appeared. Readers will recall that the first dragon was the fire-breathing accountability story of school, which demanded that student test scores meet or exceed the state mean (the dragon outside). However, the second dragon was the school story that Henry and the Eagle teachers called the relevancy dragon. The relevancy dragon was the curricular and teaching changes that the Eagle faculty were pursuing to improve students’ lived curriculum experiences (the dragon inside). Henry explained:

The first method [dragon] is “daily drip” but what we are doing is a much more honest and ethical way than simply teaching to the test ... It will take us a little longer—but we honor curriculum in our classes. We are dealing with the two accountability systems jointly as opposed to separately (Craig, 2004, pp. 1239–1240).

To give lived curriculum making the upper edge, Henry “put a circle of protection around [Eagle’s teachers] so [they] could work with students” (Craig, 2004, p. 1238). As one teacher explained,

Henry totally trusted in the professionalism of teachers. He had faith in us. He would never make us do anything perfunctory. He believed we knew best how to teach the children before us. He saw us as possessing very special knowledge of curriculum ...

(Craig, 2004, p. 1238).

Put differently, Henry Richards purposely created a context where Eagle’s teachers could live curriculum alongside their learners and where both would thrive.

However, when Eagle’s students wrote their end-of-year accountability tests, their scores did not show the dramatic increase that the school district expected. A head-on collision ensued where the two dragons—one of accountability, the other of relevancy—crossed paths. The mishap took the shape of a to-be-expected implementation dip, a phenomenon that “pacesetters and coercers ... have no empathy for ...” (Fullan, 1991, p. 40). Predictably, the school district had deaf ears when this possibility was raised. Henry Richards was called into the district office and told that “... a very prescriptive way is coming down the tubes ... The parameters have been well defined ... The reform programs are under review ... The translation of smart teachers into smart students has not taken place in the manner expected” (Craig, 2004, p. 1249). Shortly thereafter, Henry Richards “resigned” as Eagle’s principal and lead teacher. He moved up the interstate highway to work at another regional high school serving middle-and-upper-class students, a campus that greatly appreciated his insights and leadership acumen.

After Henry Richards departed, the Eagle High School students were administered another set of accountability tests the following year. In mathematics, writing and reading, their scores cumulatively increased by 25% across the board (12.6% in all tests taken), making Eagle High School a recognized campus in the state of Texas. Even more importantly, Eagle closed its achievement gaps between sub-populations (i.e., Black, Latinx), leading all other high schools in Henry’s former majority minority school district (Craig, 2004, p. 1247–1250). *Respecting teachers as curriculum makers and valuing their curriculum making alongside students made Eagle’s principal suspect in the eyes of those advancing the state accountability agenda. After the skirmish bearing serious employment consequences was over, Henry Richards maintained that how he managed the “dragons” at Eagle High School was “the honest, moral and authentic way to go”* (Craig, 2004, p. 1244). *He and the Eagle teachers concurred that “results” cannot be produced on command, especially in a high school the size of a small city.*

Stories of teacher community/teacher community stories: Laura Curtis 2002–12

The literacy teachers at T. P. Yaeger Middle School decided to adopt readers and writers workshop as their preferred teaching method. While all of them favored workshop teaching, they had mixed views concerning how their school’s wholesale adoption of the workshop would be rolled out. About half of the teachers wanted to work according to their own sensibilities; the other half favored the hiring a staff developer who would oversee their workshop implementation. Briefly, one group of teachers trusted their personal practical knowledge developed in their knowledge communities (Craig, 1995a, 2001, 2007; Craig et al., 2020a,b) whereas the other group wanted to privilege a staff developer’s knowledge over their own in professional learning communities. To make matters worse, their principal predetermined the topics around which each professional learning community would focus. As experienced teacher, Laura Curtis, explained:

Laura: The principal was in his Professional Learning Communities (PLC) groove and he wanted us to be a workshop school. Whatever we would be would be school-wide and PLC-related.

Cheryl: Was that every discussed with everybody?

Laura: It would not have been a problem, it was the way it was done by forcing people ... It was the forcing. He wanted us all as a PLC on the same page on the same day ... It has just been hard, very, very hard

(Craig, 2012a, p. 95).

Bent to the dictates of the staff developer, Laura metaphorically felt trapped like a “butterfly under a pin.” Her colleagues’ and her “slavish ... dependence on the specialist” (Schwab, 1954/1978, p. 128) meant that they no longer could make independent classroom decisions. In the past, the literacy teachers had been curriculum makers and “felt in charge of [their] teaching” (Craig, 2012a, p. 90). However, the forced curriculum change meant that everyone—even department chair Daryl Wilson—reported to the staff developer because the principal backed the staff developer and some of the literacy teachers but not the department chair and the remainder of the teachers. Unfortunately, the felt tensions came to a head on a professional development day led by the staff developer. In Laura Curtis’s words,

... it was confrontational ... everybody was confrontational. Our staff developer instigated it. It was a mean and ugly thing, something that should not be happening in a professional setting ... it just intimidated us so badly—the demeanor, the manner, the culture—what was said and how it was said ... I did not like being bullied like that

(Craig, 2012a, p. 97).

When the teachers returned to Yaeger after the weekend meeting, the teachers’ upset went up a notch. The principal stepped in, requiring the teachers to sign loyalty oaths. Laura explained how that felt: “We were under fire and we were muzzled. We had to sign affidavits. We were ordered” (Craig, 2012a, p. 97). As a result, four of 14 members of Yaeger’s literacy faculty left the campus (five member of the math faculty resigned as well) while others remained. Several of the latter took their alternate ways of living readers and writers workshop underground where they continued to tell and re-tell their counternarratives (Craig, 2020a) in the guise of cover stories (Clandinin and Connelly, 1995; Craig and Olson, 2002). This exemplar captures an epic clash at the boundaries between the two dominant teaching images and the versions of teacher community stemming from them: teaching-as-curriculum-implementer and teacher-as-curriculum-maker. *With Yaeger’s principal privileging the staff developer and the teacher-as-curriculum-implementer image, the curriculum making literacy teachers suffered a serious setback. Their identities and natural knowledge communities forcibly became imprinted with images of teaching (i.e., butterfly under a pin) and teacher community (butterflies under pins?) that were not of their making and choosing.*

Story of evaluation/value-added evaluation story: Anna Dean (2006–2012)

For the first five years of her career, Anna Dean participated in the workshop reform in the literacy department alongside Laura Curtis, an experienced teacher, and Daryl Wilson, their department chair. While metaphorically learning to teach in the “eye of a storm” (Craig 2013, p. 25), Anna was well aware of the tensions that existed on Yaeger’s bifurcated literacy faculty. She personally was of the opinion that “teachers should [not] have something forced down their throats ...” and that denying teachers’ ownership was “degrading” (Craig, 2013, p. 26). As a beginning teacher mentored by the literacy assistant principal, she “figure[ed] out that the ‘what’ and the ‘how’ are the teaching points [of] the [workshop method] ... and the connections between them are the ‘why.’” As Anna arrived at these important understandings, another experienced teacher called her “teacher-of-the-universe.” About the same time, Anna Dean announced that she had “nailed workshop.” A synergy had formed between the stories she and others (i.e., Laura Curtis, Daryl Wilson, other teacher) were telling about her teaching. After five years of induction into the workshop method, Anna achieved the highest score possible on her annual teacher evaluation. However, everything was about to be disturbed by a district superintendent change, a principal change, a literacy assistant principal change and only one of the school’s six assistant principals (the PE one) remaining on campus. Additionally, T. P. Yaeger admitted more minority-to-majority student transfers to the campus and the number of policies and procedures funneled into the campus intensified. The long and short of it was that Anna Dean who had earned her experienced teacher stripes over an extended period of time ended up being assessed by an entry-level assistant principal with no literacy background. That new administrator “victimized” Anna in what another teacher called the “value-added quota game” (Craig, 2019, pp. 20–21). The green-behind-the-ears assistant principal deducted 32 points from Anna’s previous evaluation, assigning her 3’s in categories where she previously had been awarded 5’s. Her newness to career may have made her susceptible to this kind of treatment. To Anna, her evaluation results were incommensurate with the quality of her curriculum making alongside Yaeger’s youth. As she quit the teaching profession, Anna reflected backward and said, “Cumulatively, it was too much for a veteran; much less a new teacher, but I had learned how to wade and swim backward in a sea that was slowly pulling me under. I decided to seek other alternatives for my career path ... The time had come to leave ...” (Craig, 2014, p. 107).

This close-up story illustrates how beginning teacher attrition played out for a well-mentored teacher-as-curriculum-maker. It shows how induction-year teachers risk being collateral damage when pernicious school/school district value-added teacher

evaluation formulas supported by state and national accountability policies become implemented. *Once again, the assertion that teachers can only be as good as their teaching milieus allow is reinforced—this time in the US milieu. This is especially the case in urban schools where the contexts of teaching are in constant flux due to changes in superintendents, principals and assistant principals and policies relating to student attendance and teacher evaluation, among other dictates raining down the conduit (Clandinin and Connelly, 1995; Craig, 2002).*

Image of teaching as human enterprise/image of teaching as big data: Daryl Wilson (2013–2017)

As foreshadowed, Daryl Wilson was the T. P. Yaeger's literacy department chair during the span of time when I conducted research on the campus (1997–2017). Over that sweep of time, he survived a multitude of tensions on the edges that Laura Curtis, Anna Dean and others who came before and after chronicled. Each year news form of standardization were introduced to T. P. Yaeger Middle School. For instance, after Anna Dean left, the school district mandated the use of standardized workbooks. This meant that a \$50 one-time-use workbook was purchased for every student in the school despite the literacy teachers using the workshop method, increasingly as curriculum makers. The upshot was that the teachers hid the workbooks in their classrooms. Meanwhile, another new Yaeger principal went along with their cover stories of compliant curriculum implementation. Not once did she unmask their creative rebelliousness. However, everything dramatically changed when the seventh principal in Daryl's career was assigned to Yaeger. That principal reviewed the pay-for-performance allocations received by teachers and department chairs at the school. She noted that some bonuses, while substantial, were less than previous years. Rather than attributing the evidence to Daryl teaching different students in different academic years and yielding different bonuses—or even considering that the overall school population had dramatically changed, the new principal removed Daryl from his department chair position. She also demoted another highly experienced teacher who was the grade level lead literacy teacher. When Daryl shared the sad news of what had happened to him and the other teacher, it seemed like age discrimination played a major role in the principal's theory of action. Concurrently, the administrator appeared to use big data without “[prerequisite] understandings and expertise to [make it] actionable” in defensible ways (Marsh, 2012, p. 3). Daryl Wilson was chagrined over what happened as his entire career had been devoted to advancing student learning and teacher learning through actively living the teacher as curriculum maker image. Although close to retirement, the decision to retire was not solely his own. As he left the profession to which he felt called, Daryl declared:

This is what we have come to ...

There is no other way to explain it ...

Data is [G]od ...

(Craig, 2020, p. 1).

In this experienced teacher attrition story, the privileging of decisions based on big data (even erroneously or simplistically interpreted data) superseded the value accorded teachers as curriculum makers and the knowledge generated in their emergent and ongoing communities of knowing. In the end, test data outweighed the primacy of teachers' and students' lived curriculum making, despite test data arising from instrumentalization of human experience (Muchmore, 2002), which effectively removes all of its humanity and robs it of its tears (Richards, 2020).

Trends and issues on the boundaries where curriculum implementation and curriculum making merge

This serial interpretation of what was learned from five different studies conducted over time involved lived curriculum experiences in three Grade K-6 schools in Calgary, Canada (Benita Dalton), a middle school in inner city Houston (Laura Curtis, Anna Dean, Daryl Wilson) and a high school in a Greater Houston school district (Henry Richards). As the five exemplars were unpacked, several overarching themes surfaced. One was that curriculum mandates are endlessly poured down the conduit to teachers, but teachers' ideas and solutions rarely travel upward to school district officials and state policymakers. All of the exemplars made this point in one way or another. A second theme was that those in charge (policy makers, school district officials) appeared to have only one theory of action in their playbooks: the use of power to dictate to teachers (and principals!) what they should know and do from a compliance—not a growth—mindset (Dweck, 2006). Third, the unpredictability of school and school district contexts is more-than-likely to topple best-laid plans. This was particularly the case in the four American exemplars. Henry Richards, Laura Curtis, Anna Dean and Daryl Wilson were all highly regarded in their schools; all vigorously supported lived curriculum making alongside students. However, the press for accountability played out in unimaginable ways for each of them. Even this researcher who cumulatively walked beside them had no inkling of the fates that would befall them nor the flagrant disregard paid curriculum making, which is widely recognized as the well-spring of lifelong learning (Craig, 2020a). There is little wonder that beginning (Anna Dean)

and experienced (Daryl Wilson) teacher attrition is skyrocketing, given that those with a call to teach (Hansen, 1995; Bullough and Pinnegar, 2009) are the ones who are first to abandon the profession (Yinon and Orland-Barak, 2017). Near the end of my site-based research with Daryl Wilson, his school district had in excess of 80% of its teachers with five or less years of experience and more than 50% of its principals with five or less years of experience (Craig, 2014). The fact that any middle to high performance Houston area teachers and principals would be experiencing difficulties of the proportions that Henry Richards, Laura Curtis, Anna Dean and Daryl Wilson faced is incomprehensible. It may very well be that those with thin career experiences are evaluating those with thick career experiences, which certainly seemed to be the case for Anna Dean and Daryl Wilson and possibly Henry Richards as well.

Two additional things need to be discussed: principals and surveillance. In the first exemplar drawn from my Alberta, Canada research, a principal is part of the educational hierarchy and the teachers are team teaching—pseudo-team-teaching, that is—because they know team teaching is part of their school's story. But the Alberta principal did not actively impose that agenda on them; they were hired from the outset to team teach at that district campus. Moving on to Henry Richards, he informed everyone (teachers included) about the metaphorical accountability and relevance dragons at Eagle High School and the possibility of a fracas if they sparred. Further to this, Henry favored the relevance dragon and refused to hobble the Eagle teachers by imposing the accountability dragon's agenda on them. The second-to-last T. P. Yaeger principal also turned "a blind eye" to 1500 workbooks purchased at a cost of \$7500 that were stacked up (actually "hidden in clear view" [Craig, 2020, p. 9]) in literacy classrooms. But there was one outstanding difference. In the Benita Dalton exemplar in Alberta, the principals and teachers belong to the same union and seek the same professional and classroom/school ideals. In addition, there is no financial gain attached to student performance on high stakes accountability tests in Calgary, Alberta. This is not true in Houston, Texas. Henry Richards made a moral decision to lend his support to curriculum making on his campus although he would have better served his financial gain by siding with district and state officials. Also, it is safe to say that the new T. P. Yaeger principal discussed earlier was aware of the glaring incongruences between the workshop approach to reading and writing—the campus's chosen mode of instruction—and the use of workbooks, the poster child of tradition. She too made a moral decision concerning how to proceed. However, other principals in the shared exemplars acted differently. For example, there was the early principal in Laura Curtis's and Daryl Wilson's stories who standardized the workshop approach for all teachers and students. That principal's move clipped the curriculum making wings of some teachers, dramatically defining the conflict in the school milieu for over a decade to follow. Also, Daryl's seventh principal demoted him and one other lead literacy teacher presumably because their high stakes accountability bonuses had dropped. That principal neither observed their teaching nor witnessed their interactions with other literacy department colleagues. She made her decision before the school year began. This suggests metrics may have been used in "dysfunctional and oppressive way[s]" (Mueller, 2018, p. xvii) by others in the background. Ravitch painted a possible scenario:

With sophisticated tools and capacity to do multivariate analysis, [there is] no need to enter classrooms ... Technical experts [can] evaluate teachers and schools without regard to ... actual lived experience ... what matters most [is] data

(Ravitch, 2010, p. 180).

Three other points need to be discussed. First, Diane Ravitch, mentioned above, was Assistant Secretary of Education during the administration of President George H. W. Bush. She confirmed that there is no other nation in the world except the US that evaluates its teachers on the rise and fall of students' test scores (Ravitch, 2013). Second, she recognized that countries such as Finland, Canada, Japan, and South Korea spend time and resources improving the skills of teachers, not selectively firing them in relation to student test scores (Ravitch, 2013). Third, rewarding teachers on their students' high stakes testing scores and rewarding principals on what teachers are able to accomplish with students as determined by test scores is destructive to human relationships, most especially those involving teaching, learning and supervision. Trusting relationships are nearly impossible to sustain when individuals discover that others are profiting on their labor. In addition, attention and resources can be withheld from some students and teachers in order to invest in others with a better chance of succeeding. Schwab called such orientations and enactments "bad eclectics" because they suffer from "poisoning ... at the source" (Schwab, 1959/1978, p. 171). Their root systems trace to incongruous theories and policies that limit and, in some cases, negate any positive impact they might have (Craig, 2012b).

This brings us to this chapter's conclusion. The takeaway point that the five exemplars drive home is that lived curriculum making is highly challenging and complex in the current educational environment due to the "messiness of school contexts" (Silin and Schwartz, 2003) that greatly constrains teachers' curriculum making at the juncture where it meets curriculum implementation/standardization/accountability. At the same time, it is equally apparent that positive change "depends on what teachers do and think—it is as simple and as complex as that," as Michael Fullan (2001, p. 155) phrased it. Therefore, it is imperative that this Gordian knot of teaching and teacher education (Craig et al., 2019) be untangled. Lastly, the Covid-19 pandemic stands a chance of paradoxically shifting the horizons in its own way and perhaps fueling the curriculum renaissance that Schwab (1969) foreshadowed. The timing seems opportune, given that citizens generally view teachers in a more positive light and parents are singing their praises. Further to this, the need for forward-moving educational change seems universally accepted as a foregone conclusion. Lastly, lived curriculum making accomplished through teachers' embodiments of the teacher-as curriculum-maker image (Craig et al., 2018) resonates with the American constitution whose foundation and principles are likely to be revisited on the brink of the 21st century.

Introduction

It is increasingly apparent that our collective futures will be one marked by complexity, uncertainty, and vulnerability. The shocks and shifts to our societies from global threats related to pandemic, climate change, persistent inequities, political and religious extremism, and rising authoritarianism erode social cohesion and the robustness of public institutions to counter these pressures. As we enter the third decade of the 21st century, traditional models of economic growth and the underpinnings of a globalized economy are showing serious weaknesses in addressing future challenges. Models of development and the fundamental and long held purpose of education directly linked to the economic imperative are being re-examined.

For decades now, educators have been grappling with the challenge of determining how to transition outdated school systems that were developed for an industrial age to meet more contemporary learning needs. Recommendations for transforming education include developing 21st century competencies (C21, n.d.; Battelle for Kids, n.d.), integrated use of technology, increasing creativity, innovation, and entrepreneurship (Robinson and Aronica, 2015; Wagner, 2012; Zhao, 2012) through the use of New Pedagogies (Fullan and Langworthy, 2014). Economic prosperity and community development figure strongly as a rationale for these recommendations, though individual well-being is also an anticipated outcome (Kelly, 2016; Kelley and Kelley, 2013; Robinson, 2011; Wagner, 2012; Zhao, 2012). The national and international shifts to 21st century learning are due, in large part, to well-organized, well-funded education initiatives launched by non-governmental and not-for-profit organizations. Many of these initiatives were formed with the mandate to shift education priorities in new directions and disrupt education practices initiated over a hundred years ago (Ananiandou and Claro, 2009; Brooks and Holmes, 2014; C21, n.d.; Center for Educational Research and Innovation, n.d; Fullan and Langworthy, 2013, 2014; Battelle for Kids, n.d.).

However, quickly shifting global realities have rendered even these most recent efforts to reframe, reimagine, and transform education for the 21st century clearly wanting. Just a few years ago, proponents of 21st century teaching and learning called for “radical” (Fullan and Langworthy, 2014, p. 4) makeover of education for the perceived challenges and demands of the 21st century. Educators have turned to real-world design projects that require creative, critical problem solving, collaboration, communication, and integration of content knowledge, new learning, and skill development. Large multi-national tech companies and Silicon Valley billionaires have taken special interest in American K–12 education and are investing large sums of money to re-shape the classroom for 21st century learning goals (Singer, 2017a,b; Strauss, 2020).

While 21st century education initiatives are focused on competencies, dispositions, and work habits to prepare students for the future, in almost all cases an explicit discussion of the fundamental purposes and aims of education and what our common future will look like is avoided. Rather, in the discourse of 21st century skills development, the purpose, or aim of education, is implicit. Education is designed to meet functional ends—to develop creative, innovative, life-long learners, to solve the world’s problems, to answer the challenges of shifting workforce demands, and to develop good citizens. Few of these recent endeavors to transform K–12 education have incorporated what it means to educate for a world of increasing complexity, uncertainty and fragility. Instead they essentially aim to ensure that students are prepared for success in a fast-changing world—presumably contributing to the outdated and unsustainable economic patterns that rely on the over consumption of non-renewable resources and environmental degradation.

The purpose of this article is to situate any re-visioning and re-framing of education, classrooms and curriculum around the concepts of life and living. In this way we trace the concepts of a living curriculum in living schools (O’Brien and Howard, 2016, 2020) to its roots. We understand coalescing schooling around an ethos of life and human flourishing as a radical idea that has been cross-pollinated by rich and deep traditions of progressive education going back over a century. As we will see, reframing education and schooling for the future that awaits us is profound, far-reaching, and fundamental. In this article, I will demonstrate that the vision of a lived curriculum is closely related to initiatives characterized as 21st century teaching and learning but with an important difference. In a living school, the curriculum, the approaches to instruction, the physical environment, and the relationships between and among students, teachers, parents, and the community are guided by an ethos that is life-affirming. It reflects a way of being and becoming that roots education in what the philosopher McMurtry (1998) calls a “life-code of value” and situates the school in a living community of relations.

Living schools re-conceptualize education for our times and for future human flourishing. Such schools do not retreat from explicitly articulating a response to the question, “What is education for?” Historically, educational approaches, trends, and initiatives, including 21st century teaching and learning, have largely avoided engaging explicitly with *the* why of education. Commonly stated purposes of education most often align with raising test scores, helping students achieve by becoming better learners, and preparing students for emerging labor markets. These aims of schooling often deflect from deeper questions of the larger purposes of education and how we “navigate plural realities across communities in both the North and South” ([International Commission on the Futures of Education, 2020](#), p. 2). Without doubt larger purposes can be teased out of discussions of 21st century teaching and learning. The result of this effort invariably discovers that the why of education reflects a set of functional outcomes identified with an economic value system that in many ways commodifies the lives of students and “shapes the selves of learners in accordance with what are perceived to be current economic imperatives, rather than, say with what arises out of their sense of their own existence” ([Bonnett, 2009](#), p. 358).

Education cannot be simply framed in terms of economic growth; human flourishing and the accessibility of lives of purpose and dignity must be primary concerns. As we come to terms with the anthropocene as a geological era of human-caused change to the planet the key question before us is: what do we want to become? This is a question to be asked and answered through education ([International Commission on the Futures of Education, 2020](#), p. 1). Before we explore this more fully, let us look ahead by first looking back to discover the roots of a lived curriculum as a concept grounded in the traditions of progressive education. We will then look at education for sustainability and 21st century teaching and learning as important influences on the concept of a living school. Finally, we will examine what sets a living school with a lived curriculum apart from previous approaches by exploring how life values and sustainable well-being represent a profound and radical shift toward the kind of education required now and for the future.

Progressive education

Progressive ideas can be traced to the earliest writings about education. In the Western tradition, and particularly in the United States, pragmatist philosophers Charles Sanders Pierce, William James, and most notably John Dewey influenced progressive educators. [Dewey \(1938/1997\)](#) showed that complexity and change meant that education could not be reduced to formulaic preparation for life; it needed to be life itself, messiness and unpredictability included. Progressive educators looked for ways to realize Dewey’s vision through valuing diversity, building on the interests of students, organizing learning in larger more holistic units, connecting school to the surrounding community, and developing citizenship.

The central tenets of progressive education were formalized in 1919 at an organizational meeting of the newly created Progressive Education Association (PEA) in Washington, DC ([Little, 2013](#)). The founding principles were based on Dewey’s writing and research. Dewey ran an experimental school on the campus of the University of Chicago in the 1890s and into the turn of the 20th century. For Dewey, education connected to the vitality of life and living was the “great thing” ([Dewey, 2009](#); as cited in [Waks, 2013](#), p. 79). Dewey wrote,

We cannot overlook the importance for educational purposes the close and intimate acquaintance got with nature first hand with real things and materials, with the actual processes and their manipulation ... no number of object lessons can afford even a shadow of a substitute for acquaintance with plants and animals of the farm and garden acquired through actual living among them and caring for them.

[Dewey \(2009\)](#), as cited in [Waks \(2013, p. 79\)](#).

The reality of life in nature as the great thing is an enduring theme throughout Dewey’s writings. Progressive schools were community-based and connected to the life of the neighborhoods in which they were located. They promoted child-centered learning in which the unique self of the student was nurtured to meet their full potential. As we will see, the shadow of progressive education looms large in more recent initiatives, such as Education for Sustainable Development ([McKeown, 2002](#); [UNESCO, 2019a,b](#)). In *The School and Society* (1900/2009) Dewey included diagrams and designs based on his work at the Laboratory School in Chicago. The neighborhood, gardens and fields, businesses, and the university surrounded the school and connected the students to the life of the real world. Teaching and learning areas replaced traditional classrooms and the natural environment was connected to these learning areas. Gardens and fields supplied fresh food for the kitchen, another important learning area associated with learning for the occupations. More recent educational approaches, like the emergence of project-based learning (PBL) ([PBLWorks, 2018](#)), are also artifacts of progressive education re-purposed for today. The roots of PBL are found in *The Project Method* written in 1918 by William Heard Kilpatrick. John Dewey, a fellow faculty member at Columbia Teachers College at the time, introduced Kilpatrick to the method.

Innovative, progressive schools flourished in the US, Canada, and elsewhere until the 1950s then they waned and virtually disappeared. There was a resurgence in the 1960s and 1970s with the Open School concept, and indeed some progressive schools continued and are highly successful to this day. However, a conservative turn in the 1950s, rising concern of losing economic ground during the Cold War, and the emergence of a globalized economy combined with powerful ideological influences of neo-liberal and corporate elites largely sounded the death knell for progressive education. Transmissive teaching, traditional instruction, standardized curricula, measurable inputs and outputs in the form of learning outcomes, large-scale testing, and harsh

accountability regimes transformed Western education in the second half of the 20th century. The progressive purposes of education, the development of the child as a human-being-still-becoming were largely transplanted by commodifying the child's self in the service of the economic system.

While no one is advocating for a return to the schools of the 1930s, it is instructive to situate today's 21st century teaching and learning in the narrative of a longer educational story that leads to the concept of the Living School. Dewey and the other architects of progressive education were 19th and early 20th century people. The "why" of education for them was influenced by the historical and cultural realities of that time. The aim of education was to counter the destructive influences of the juggernaut of industrialism that was transforming society, displacing communities and households as the centers of production, and responsible for mass urbanization and global migration into cities. The factory model was powerful in shaping all aspects of life including schooling. The progressives countered these forces with a focus on individual development through experiential, real-world learning that strengthened community, cooperation, civic mindedness, and the democratic ideal.

Early in the 21st century we face different challenges for which our education systems also seem unsuited. Globalized systems, rising levels of inequity between rich and poor, and social, economic, technological, and ecological change are unprecedented, and the disruption is keenly felt at all levels. Again, we look to education for a response. The education initiatives of 21st Century Teaching and Learning (Griffin et al., 2011) and Education for Sustainable Development offer skills and competencies enhanced by emerging digital technologies that will prepare learners for new realities. The past preoccupation with raising test scores through standardized curricula and testing has been deemed a failure for developing the creativity, innovation, problem-solving, and critical thinking required to flourish in this new century (Ravitz et al., 2012). Each initiative signals a re-emergence of progressive ideals, but for very different purposes, and each has influenced the Living Schools concept. Let us begin by looking at Education for Sustainable Development.

Education for sustainable development

If there is one recent conceptual approach to organizing education to which the living school with a lived curriculum can be most directly linked it is Education for Sustainable Development (ESD). The overarching paradigm of sustainable development is based on greater equity between individuals and groups that is realized through values related to social justice, poverty reduction, and systems thinking that understands environmental, economic, and social interests as being inextricably intertwined (McKeown and Nolet, 2013). ESD was born out of the Earth Summit in 1992; Chapter 36 of the Agenda 21 (United Nations, 1993) document presented a vision of the world's education systems educating in ways that would lead to a more sustainable future. ESD, or Education for Sustainability (EfS) has emerged as a progressive approach to teaching and learning that is locally relevant, culturally appropriate, and addresses all realms of sustainability (environment, society, economy). In this regard, EfS is action-oriented and promotes similar competencies as 21st century learning (Council of Ministers of Education Canada, 2012; United Nations Economic Commission for Europe [UNECE], 2012); however, with the explicit vision "to help communities and countries meet their sustainability goals and attend to the well-being of the planet and all its living inhabitants" (McKeown and Nolet, 2013, p. 7). The Sustainable Development Goal 4 encompasses education for sustainability (UNESCO, 2019a,b) and situates education and knowledge as part of the living heritage of humanity in an interdependent world and a common global good (UNESCO, 2016).

ESD approaches are steeped in the tradition of progressive education. The child's experience is central and the importance of building on the experience of the student is recognized. Through dialog, experimentation, and engagement with real-world issues and projects, young people are able to clarify their own and others' worldviews and to recognize alternative frameworks and futures exist. The focus on experiential learning, individualized instruction, deep learning, real-world application, cooperative learning, and creating learning tasks with direct relevance to students' lives mirrors progressive ideas. However, ESD articulates unequivocally a larger purpose for education that Dewey and his contemporaries perhaps would not have been able to envision. "ESD helps develop the capacity for critical reflection and systems and futures thinking, as well as motivate actions that promote sustainable development" (UNECE, 2012, p. 7). ESD is aimed directly at allowing education to prepare the next generation with the skills, knowledge, attitudes, and values to address our most challenging issues. And yet it is in that language there exists what has become the most strident critique of ESD, and that is the term sustainable development. A full critique of EfS is beyond our scope here but suffice to say that the term development and the word sustainability have become problematic. It has been argued widely that these words have been co-opted by powerful corporate and economic interests to ensure status quo values, attitudes, and economic systems largely responsible for the ecological and societal challenges we face are, in effect, sustained. Jickling and Sterling (2017) ask, "Is sustainability the most useful term—the term that stands to create the most effective critical traction—to serve educational interests?" (p. 3). It is a fair question.

21st century teaching and learning

Global efforts are underway to re-conceptualize K–12 education for what is commonly known as 21st century teaching and learning. The international shift to 21st century learning is due, in large part, to numerous reports and white papers published in the last decade and well-organized, well-funded education initiatives launched by non-governmental and not-for-profit organizations. Many of these initiatives were formed in partnership with large corporations with the stated mandate to shift education

priorities to new education goals and disrupt deeply embedded traditional education practices (Ananiandou and Claro, 2009; Brooks and Holmes, 2014; C21, n.d; E21C, 2017; Fullan and Langworthy, 2013, 2014; P21, 2016).

Like ESD, 21st century teaching and learning approaches are progressive. To support the “radical” reformulation of education (Fullan and Langworthy, 2014, p. 4) for the challenges of the 21st century, educators have turned to real-world design projects that require creative, critical problem-solving, collaboration, communication, and integration of content knowledge, new learning, and skill development. The increase in popularity of the Maker Faire Movement (Kelly, 2016), a Do-It-Yourself (DIY) ethos (Knobel and Lankshear, 2010), robotic competitions, hack-a-thons, problem- and project-based learning (PBL), all enhanced by sophisticated information and communication technologies (ICTs), provide identifiable approaches for the application of the creative process. These learning opportunities offer accessible strategies and recursive steps to develop 21st century learning competencies (Stanford University School of Design, 2016).

21st century teaching and learning offers exciting, engaging learning for students and promotes strong relationships between teachers and young people as co-learners. The initiatives represent a moving away from traditional education approaches that are transmissive, controlling, authoritarian, and demanding of compliance in behavior and thought. The focus on creativity and imagination, collaboration, and critical thinking is hopeful, as is the renewed emphasis on the importance of student-teacher relationships. These are positive developments.

The radical change proposed by advocates of 21st century skills adheres to the dictionary definition of the word, a “thorough or extreme change to traditional forms” (Radical, 2013). But the word “radical” means something else. Words can lose their lived meaning through overuse and paying close attention can re-vitalize the language and connect us to the lived experience to which the word was originally tied. The word radical is charged with the political and the subversive. Calling for radical change in education is done for intentional effect. The word came from the Latin “radicalis” and meant “the direct source or sense” (Ayto, 1990, p. 428). It is a word rich in depth and nuance as it is related to roots and rooting. In medieval philosophy, the radical humor was inherent in all plants and animals, its presence being a necessary condition of life. It is this sense of the word radical is invoked regarding education reform; it is the word’s connection to the fundamental, primary, essential condition of life that may help us respond to the question of “radical change in education, for what purpose?” When the goals of education are aligned with an ethos of life and living, the fundamental question of what we are reforming education for can be posed as a counterpoint to the functional, future-oriented, technology-enhanced belief in education for its neo-liberal, economic, career, and problem-solving purposes.

Looking carefully at recent documents that espouse transforming education for the skills of 21st century learning provides a clearer sense of the demands placed on education. The international project New Pedagogies for Deep Learning: A Global Partnership (NPDL), led by Canadian education consultant and scholar Michael Fullan, is well funded and highly organized, and includes partners from multinational corporations like Intel, Microsoft, and Pearson Publishing (NPDL, 2019). NPDL is working with “clusters” of schools in each of seven countries. The goal is to build collective capacity within and across education systems and “to call to action, engage partners in the common purpose to mobilize deep learning, capture and cultivate new pedagogies that advance deep learning, and continuously measure and analyze what is working” (Fullan and Langworthy, 2013, pp. 19–20). The NPDL white paper *Toward a New End: New Pedagogies for Deep Learning* (Fullan and Langworthy, 2013) begins by describing “the crisis” in public education, namely student disengagement and teacher frustration. Fullan and Langworthy (2013) explain the crisis in education is “intrinsic to our societies’ transition to knowledge-based economies and global interdependency, enabled and accelerated by technology” (p. 1). The authors add, “Amid the challenges, we have begun *defining the what*: new goals for learning relevant to this new era. However, the immediate and expansive attempts to *innovate the how*; the process of education—are urgently required” (2013, emphasis in original, p. 1).

While the “what” and the “how” of education are the central concerns of the ambitious global initiative, the “why” is less well developed. Fullan and Langworthy (2013, 2014) attempt to address the “why,” the larger purpose of the global education reform initiative, by explaining that the NPDL partnership,

seeks to renew our goals for education and learning to include skills that prepare learners to be life-long, creative, connected problem solvers and to be happy, healthy individuals who can contribute to the common good in today’s global interdependent world. We need learning systems to encourage youth to develop their own visions about what it means to flourish and equip them with the skills to pursue these visions (2013, p. 2).

On the surface this seems to be perfectly reasonable. Who would not want children to be happy, healthy, flourishing people equipped to be successful in a complex and changing world? Yet, a claim like this becomes problematic when framed in the language of crisis and in an apparent value-neutral way that leaves young people to “develop their own visions” about what it means to flourish and “contribute to the common good.” In this way, the authors avoid the “why” of education for an instrumental, functional view tacitly related to “happiness, health, and flourishing” but the larger vision is never fully articulated.

The virtual absence of a purpose for learning, and a reluctance to articulate that to which the learning points, is problematic (Howard, 2018). A functional bias toward preparation for the knowledge economy, a fear of being left behind in a competitive global race for economic dominance is betrayed in Fullan and Langworthy’s language describing teachers as “human capital” who have “social capital (the relationships with students, parents and community)” and “decisional capital (negotiating the challenging learning experience)” (2013, p. 13). The language of “capital” has symbolic and rhetorical power. It speaks to the tacit

purpose of education reform for 21st century learning—to protect and strengthen the social and economic status quo firmly anchored in a market-based, competitive economic ideology. It is in this sense that the education transformation 21st century learning intends to represent is not the *radical rethinking* of education it positions itself to be.

Living schools and the purpose of education

The pioneers of progressive education working at the end of the 19th and early decades of the 20th century were responding to the social, political, and economic realities of their day. The larger purposes of education, as the progressives envisioned them, were shaped by strong democratic principles and the values of equity, diversity, the importance of individual freedom, agency, and experiential learning for human becoming. The education they worked hard to attain was at cross-purposes with the powerful market-driven values of schools as training grounds and labor pools for a burgeoning industrialized economy. The echoes of the factory model of schooling can still be heard today in the ringing of bells and buzzers to move students en masse; it can be seen in neat rows of individual desks, felt in the asphalt and chain-link of school yards, and understood in fragmented curricula cloaked in the language of fragmented learning outcomes and standardized test scores.

Today we face issues and challenges that would be unimaginable at the turn of the last century. One of most pressing existential questions for education that is generative and generational is how humans as a species will continue to live well, and sustainably on this planet. David Orr (1992) presents succinctly a purpose and vision for education in which the goal is not merely deeper learning and new pedagogies but learning *toward* life, making connections, and being explicit about what do we want to become. Orr (1992) writes of his vision for education:

First, it aims toward the establishment of a community of life that includes future generations, male and female, rich and poor, and the natural world. The essence of community is recognition, indeed celebration, of interdependence between all parts. Its indicators are the requisite sustainability, peace, harmony and justice and participation (p. 138).

Orr is advocating for a vision of education that is progressive but also encompassing, expansive, generous, affirming of all life, inclusive of the more-than-human, and reaches toward a place of deep transformation. The discourse of 21st century learning is one in which there is confidence and power, a techno-optimistic, and future-facing resolve that education, or more aptly, learning, specifically deep learning, will conserve a way of life founded on intensely held cultural beliefs about progress, growth, development, competition, and technology. Education has not been a panacea for the world's ills; as education levels rise so too do the myriad issues related to unsustainable consumption and inequities in the distribution of wealth. Students will only “develop their own visions about what it means to connect and flourish” (Fullan and Langworthy, 2013, p. 2) when educators, researchers, policy-makers, and all stakeholders radically deepen a sense of interconnectedness, earth-centredness, and humility that are both accepting and mindful of the paradoxical relation of the flux, uncertainty, and unpredictability of life.

Living schools with a lived curriculum are created on a shared vision for education that is life-forwarding. It is a vision of education that differentiates between what the philosopher McMurtry (1998, 2002) calls the life-code of value versus the money-code of value. He characterizes the dominant economic system that has fully been absorbed into culture, policy, government, education and our daily understanding of “reality,” as a system that promotes money and the market above all else. McMurtry (1998) describes the dominant market system as a value code “that underlies people’s normal decisions and actions [and] is one that affirms more money revenues as good and rejects less money revenues as bad” (p. 297). He calls this largely unquestioned principle of value and disvalue the *money-code of value*. It is represented simply as.

Money → Commodity for Sale → More Money.

Money is the beginning and the end of the sequence. In opposition to the money code of value, McMurtry (1998, 2002) proposes the life-code of value. The life-code of value is represented by the following sequence.

Life → Means of Life → More Life.

McMurtry defines life as “organic movement, sentience, and feeling, and thought” (1998, p. 298). Means of life is “whatever enables life to be preserved or to extend its vital range on these three planes of being alive” (p. 298) such as clean air, water, nutritious food, shelter, affective interaction, environmental space, and accessible learning conditions. Maintaining these conditions reproduces life; augmenting and deepening them increases life-value. Essentially, it is life-forwarding and life-affirming. The codes of value—money and life—are different in that in the money-code of value money is the beginning of the value sequence and money is the end of the sequence. “More money,” says McMurtry (1998), “and not more life is the regulating objective of thought and action” (p. 299). The more money that returns to the investor regardless of what happens to life, the better the investment.

Life values are beginning to re-assert themselves and it is these values that must guide discussions of 21st century education. McMurtry’s life-code of value offers a theoretical construct for an alternative value system with which most people are already familiar. It manifests itself in people’s lives everyday as the civil commons. The civil commons are what people come together to protect as distinct from the money-code of value logic. Universal health care, parks, green spaces, volunteer service groups, fire protection, clean water, food inspection, good government, a justice system, libraries, and public education are all examples of what we believe are life-based and life-protective. These are, as part of the civil commons, oriented to life values, not money

values. Commodifying any of these or attempts to turn them over to market-based, private, for-profit entities are met with great debate and resistance. These are all life-affirmative forms of capacity building and allow society to protect and enable open access to life goods or the means to life.

These are values built on human agency and enable access for all community members, not just a privileged few, to grow and express themselves. The community may be local, national, or global. In a life-code value, education is a life-good, both public and individual, and is not a commodity. Children and young people are not commodified learners, future knowledge workers, consumers, or human capital. Children are on the path of human “becoming.” They need pedagogical relationships with teachers entrusted to lead them in search of meaningful lives and the beauty of their full potential as flourishing individuals.

Living schools understand themselves to be in the service of life, and a life-code of value speaks to larger purposes that form the ethos of the school. In a living school, teaching and learning take on new meaning and vitality when allied with a life-affirming purpose. 21st century education is inherently experiential and working experientially offers a way to formulate alternative interpretations of reality, interpretations based on our felt contact with the world, that can challenge taken-for-granted historical and cultural beliefs largely shaped by the money-code of value. Education in a living school is interactive and dialogic. Building an experiential sense and involvement in the community of life develops awareness of how we are connected, interdependent, and intertwined, undoing an individualistic, competitive, isolating experience of the world. The experiential pedagogies of 21st century deep learning and progressive education, when aligned with a larger purpose as reflected in the life process, give authority to our experience. The emotional and physical well-being of both teachers and students can be supported through the open sharing of experiences that move toward actions that are *for* the life process, rather than against it—and that work to embrace all of the living world.

Living schools embody an ethos of bringing life to education and education to life. This means that the values of well-being for all (Hopkins, 2013; O’Brien, 2016) influence what is learned, how it is learned, where and when it is learned, and ultimately *why* it is learned. Living Schools demonstrate the inspiring and dynamic transformation that is possible when the foundational purpose of education is questioned, and the answer is that it ought to lead to well-being for all sustainably. This is both a radical reformulation of education as well as one that draws on longstanding views that education must be experiential (Dewey, 1997, p. 39), that respects holistic world views at the heart of many Indigenous cultures (Deer and Falkenberg, 2016), and that recognizes new pedagogies also include wisdom traditions associated with mindfulness and land-based learning. Living Schools bring a coherent perspective to the diverse and sometimes divisive efforts to reimagine education. These schools take us beyond a collection of social justice or environmental projects, which are laudable, but are not propelling a timely transformation of education.

The focus on well-being ensures that living schools support outdoor learning, social-emotional learning (Collaborative for Academic, Social, and Emotional Learning, 2012), positive education, and Health Promoting Schools where staff and students flourish (Joint Consortium for School Health, 2008). The presentation of a complete theoretical rationale for living schools and an explication and illustration of the attributes and practices indicative a living schools framework are beyond the scope of this article. However, this work can be found elsewhere as practical, professional research and resources (O’Brien and Howard, 2020; Howard and O’Brien, 2017; O’Brien and Howard, 2016).

Education in the service of life has, as its fundamental goal, the life-forwarding steps that emerge from making authentic contact with the world. This re-visioning and reframing of education takes advantage of the creativity inherent in the life process, the uncertainty, the new meanings, and the possibilities that arise with the unfolding of experience. Organizing schools with a lived curriculum based on life-forwarding principles grounded in the world - the social world, the human-built world, and the natural world—can foster contact and dialog *with* the world and, in so doing, schools become living schools that organize learning in ways to enhance *well-being for all*, sustainably. It is in this way that schooling re-conceptualizes education for our times and for future human flourishing.

Introduction

The world of education is changing before our very eyes. The impacts of the COVID-19 pandemic around the globe continue to create monumental shifts in the ways that education is delivered and envisioned. In our contexts—urban United States and rural South Africa—impacts of the COVID-19 pandemic are exacerbating structural inequities in our educational systems. That is, access to education is becoming increasingly challenging for communities that are the most vulnerable. To be clear, such inequities existed long before COVID-19. For example, both in South Africa the United States, teachers work in the contexts of shifting ethnic demographics of students. This significantly influences classroom teaching as teachers work alongside growing heterogeneous student populations with different ethnic, racial, social class, cultural, and linguistic backgrounds. In 2020, and with the onset of the COVID-19 pandemic, discrepancies associated with issues like access to remote learning, shelter in place, and safe learning contexts are under a new, intensified spotlight.

A central figure in these tumultuous educational times is the teacher. In many places, teachers are literally on the front lines—facing the challenges of a sea change in the ways that teaching and learning are created. In our work as teacher educators, we honor and acknowledge the tremendous work of teachers and place great value in the ways that their lived experiences shape the curriculum they deliver and impact the students they serve. In this article, it is our hope to portray ways in which K-12 and college teachers live their curriculum through critical pedagogy and action research.

Neither of these approaches—critical pedagogy and action research—are novel concepts in teacher education. Yet, we feel that when they are combined and infused within teacher training and support programs, they provide an important framework for teachers to generate meaningful curriculum, study their own pedagogy, and continually refine their practice in relevant ways. We believe that it is this type of praxis (Freire, 1970) that can foster the ingenuity, passion, and transformation that teachers bring to their work. We also feel that through highlighting the work of teachers in an article and a volume like this, we center their role in the changes before us in the field of education. Too often, teachers' voices are silenced in the narrative about educational reform, and too often teachers' experiences in classrooms are minimized to routines and strategies (Pour-Khorshid, 2020). We know—from our work as and with teachers for the past twenty-five years—that teaching is far more than a practice. It is a lifelong process rife with intellectual rigor and tenacity. By highlighting the ways in which teachers live their curriculum, we hope to honor the complexity of the work they do and their positive impact on young people and our society at large.

We hope to showcase the deep, reflective, and iterative work of teachers through presenting a conceptual framework that focuses on teaching for social justice (e.g., Nieto, 2002) through culturally relevant pedagogy (e.g., Ladson-Billings, 2016). In presenting this framework, we intend to explore some of the true purposes of education and the ways in which classroom teachers are the conduits for change in local communities (Freire, 1970). We then apply aspects of action research as a pedagogical and scholarly process that teachers engage in alongside their students to assess, reflect upon, and enhance their teaching. In the second half of the article, we present two case studies—from each of our local teaching contexts—to showcase examples of teachers enacting culturally relevant pedagogy and action research with young people. Our goals in describing and discussing these examples are to share the work of the inspiring teachers with whom we work in hopes of sparking dialogue, critique, and further innovation in our own and in other teachers' classrooms.

Theoretical framework

Education for liberation

As professionals, we take great pride in the roles we get to play in the educational system. We deeply believe in the transformative possibilities of teaching and learning, and we feel blessed to work alongside teachers and youth who will be the leaders of the future. We also hold strong critiques of the educational systems in our respective countries and communities because it is undeniable that schooling as we know it reflects and reproduces structural inequities in our society (Kumashiro, 2020; Rist, 1970). Formal education has been and continues to be a forceful tool used by those in power to promote assimilation and conformity (Emdin, 2016; Woodson, 2000). We do not feel that this critique dampens our faith in the value of education; instead, we believe that this type of critical social analysis is important in our systems as a way to envision and foster change.

We seek to build upon foundational theories and conceptualizations of education as a human right and a vehicle for social transformation within communities (e.g., Foucault, 1977; Giroux, 1992; Zinn, 2003). Our educational systems—and the very ideas of students, teachers, and classrooms—are part of a larger vision of meaningful learning, self-reflection, and action within communities for the purposes of change for and by those in the community. That is, we seek to follow Freire (2000) call for a form of education for liberation:

Education either functions as an instrument which is used to facilitate integration of the younger generation into the logic of the present system and bring about conformity or it becomes the practice of freedom, the means by which men and women deal critically and creatively with reality and discover how to participate in the transformation of their world (p. 34).

Heeding this call requires continual self-interrogation, a belief in the agency of teachers and students (including the co-construction and fluidity of these roles), and true commitment to a life-long learning process that centers critical consciousness and dialogue (Freire, 2000).

As teacher educators, we are continually learning from our students, who are continually learning from their students. We are part of a cycle of teaching and learning that must strive to stay culturally relevant amidst constantly evolving cultural contexts. As scholars, we feel that it is our responsibility to document and disseminate these learnings and teachings across academic settings and disciplines. We are keenly aware of many of the tensions and challenges inherent in this work. For example, as teachers of teachers, we do not fashion ourselves as experts. We do not proclaim to have answers for fixing the structural inequities in our schooling systems. Instead, in this article, we are attempting to present a framework and portray the work of classroom teachers as parts of a larger vision for meaningful changes in education and in society.

Culturally relevant pedagogy

As teacher educators, we are acutely aware of the importance of adopting and adapting culturally relevant pedagogies. We believe this develops our own and our students' knowledge, attitudes, and skills which contribute not only to academic and social empowerment but also to emotional and political empowerment. We also feel that embracing culturally relevant pedagogy allows us to teach effectively in classrooms that are culturally diverse. As teacher educators, we seek to bridge the cultural divide, and therefore integrate knowledge of our students' cultural backgrounds in our teaching. That is, we strive to adopt Ladson-Billings (1995) notion of a culturally relevant pedagogy:

... that not only addresses student achievement but also helps students to accept and affirm their cultural identity while developing critical perspectives that challenge inequities that schools (and other institutions) perpetuate (p. 469).

Like Gay (2000), our culturally relevant and responsive pedagogy takes into account "the cultural knowledge, prior experiences, frames of reference, and performance styles of ethnically diverse students to make learning more relevant to and effective" (p. 29). Our teaching is underpinned by Ladson-Billings (2014) three principles of culturally relevant pedagogy: academic achievement, socio-political consciousness and cultural competence. We agree with Ladson-Billings (2014) that culture is fluid and that we should take "previously developed ideas and synthesize them to create new and exciting forms" (p. 76). We believe that it is important for teachers to consider teacher knowledge and reflection when they design and implement culturally responsive lessons. In accord with Howard (2003), we argue that critical reflection about culture and race of teachers and students is essential in order to develop teaching strategies that are culturally relevant. Over the years, we have attempted to develop culturally relevant pedagogy and have tailored our teaching to the textual, social, cultural, and personal dimensions of our students' lives (Hefflin, 2002). We believe that culturally relevant pedagogy should have the following outcomes: empowerment, incorporation of culture in curriculum and teaching, and meaningful understanding of socio-political realities in society and how society works (Milner, 2011).

It is our hope that our teaching of a culturally relevant curriculum, will inspire and encourage our students to revise their classroom teaching to be more culturally relevant. We envision that a culturally relevant curriculum will serve as a vehicle to transform society to be more just and equitable. And in the context of today's rapidly-changing educational terrain, we feel that our own and

our students' abilities to strive for cultural relevance in teaching requires deep personal reflection, continual pursuit of enhanced critical consciousness, and active dialogue.

Action research

The last twenty years has seen exponential growth in interest in action research as more teacher educators and teachers engage in action research in various forms—including university credit-bearing courses and modules, professional development, and plans or projects to restructure schools and curriculum. As university teachers, we believe that action research forms an integral aspect of teacher education and is a key driver in educational change and professional development. According to Carr and Kemmis (1986), action research is:

... a form of self-reflective enquiry undertaken by participants in social situations in order to improve the rationality and justice of their own practices, their understanding of these practices, and the situations in which their practices are carried out (p. 162).

We are of the view that action research has the potential to bring about change in specific university, school and classroom contexts. That is, we are guided by Mills' (cited in Hagevik et al., 2012) notion of action research as:

any systematic inquiry conducted by teacher researchers, principals, school counsellors, or other stakeholders in teaching or learning to gather information about how their particular schools operate, how they teach and how well their students learn (p. 675).

As educational professionals, we believe that the principles and processes of action research provide us with information to improve facets of our day to day teaching practice. We heed the call of Kemmis (2006) and adopt a critical approach in action research. In adopting this critical approach to action research, we seek to foster in our students a critical edge aimed at transforming their social contexts and lived experience instead of accepting conventional ways of schooling and society. That is, we encourage our students, who are teachers themselves, to study their social situations and classroom contexts in order to improve their understanding of their practice as well as the quality of their teaching practice. We showcase how teachers engage with action research in their classrooms with their students and argue that this serves as a powerful teacher professional development activity to empower teachers and transform their practices.

Teachers in our case studies participated in the cyclical process of action research which comprised the steps of planning, acting, and observing, with reflection in all the steps (Macintyre, 2016). Our students were also acutely aware that action research refers to repetitive cycles of reflection comprising the following steps: planning a change, acting, and observing the process and consequences of the change, reflecting on these processes and consequences and then replanning, acting, and observing, reflecting and then repeating the process (Kemmis and McTaggart, cited in Koshy et al., 2011, p. 5). We believe that action research helps us and our students to find solutions to the challenges we experience in our teaching and brings about a positive change. That is, we support Koshy et al. (2011) assertion that action research involves problem solving, especially if the resolutions lead to improvements of practice. As professionals, our students conducted action research within the confines of their classrooms, to produce context-specific data about teaching and learning. It is our hope that through action research, both teacher educators and teachers are better able to adopt culturally relevant pedagogy and understand how it contributes to the lived curriculum in a globalized world.

Teachers living their curriculum

Below, we present two different examples of the work of teachers engaged in action research from our own cultural contexts. These cases are not intended to make generalizations about teachers, communities, or pedagogies but to provide examples of ways that teachers with whom we work develop and reflect upon their own practices. Additionally, we do not present these cases to portray a monolithic approach to culturally relevant pedagogy or action research. It is our hope that these examples can create dialogue and offer ideas for other teachers and educators.

Notes to Mr. G.

Mr. G. is a Fourth-Grade teacher in public elementary school in a large, urban school district in California. He is in second year of teaching and he lives and works in the community neighboring the school. In fact, it is the community where he grew up. Mr. G. identifies as Asian-American as do the vast majority of his students (nearly 80%). He also has students who identify as mixed-race, Latina/o, African American, and White. Mr. G. is passionate about building meaningful relationships with his students and cares deeply about fostering their unique interests and needs. Mr. G. reflects that much of this passion comes from his memories of his own schooling. He feels that there was so much pressure from his teachers and his parents to learn English quickly, become

a strong reader, get good grades, and excel on tests, that he never really thought about school as a place that he felt comfortable being himself.

To pursue this goal of relationship-building as a foundation of his teaching, Mr. G. wrote his Master's thesis on an action research project that he developed called "Notes to Mr. G." This project is an ongoing process for Mr. G.—he created it as a student teacher and continues to refine it during his first few years of full-time teaching. The premise of "Notes to Mr. G." is simple—it is an interactive journal that his students keep throughout the school year. At the beginning of the year, students design their own journal and Mr. G. tells them that their journal is theirs to keep and that it will not be graded; it is a tool to express themselves and work on their writing. Students design the covers of their journals to make them unique and they generally write 2–3 entries per week during the school day. On Fridays, Mr. G. takes the journals home with him, reads some of the students' entries, and writes back to them in the journal. The prompts for student writing range from free writing time (students get to choose to write about whatever they like) to fun/creative topics (e.g., "If you could have any animal as a pet, what would you choose, and why?") to school/classroom topics (e.g., "Do you think students should be able to bring phones to school? Why/Why not?") to current events (e.g., "What does the Black Lives Matter movement mean to you?"). Mr. G.'s written responses are not focused on technical aspects of students' writing, but rather are conversational—often asking students questions as follow up or sharing his own interests about a given topic.

As a process, "Notes to Mr. G." is an iterative, informal form of communication between student and teacher. As an action research project in which Mr. G. studies students' journals, his written responses, student learning, and his own learning, he is actively engaged in praxis through authentic dialogue—students come to learn about and trust Mr. G. just as he learns about and builds relationships with them. He then actively shapes his pedagogy and his curriculum through what he learns from the journals and his experiences with students in class. After studying one full year of "Notes to Mr. G.", he realized that students were opening up with him more and more. He was learning about parts of their identities that typically were not a part of classroom learning. For example, he learned about their passions for gaming, drawing, dancing, and wrestling through journal interactions. He also learned that they wanted to know more about him—they would often respond to his written questions with questions of their own. He learned that he was being more open with his student than any of his K-12 teachers were with him. He learned, even, about working through meaningful discussions with students (through the journals and through in-class conversations) about setting boundaries and respecting different people's privacy and individuality. As a representation of living and learning through the curriculum, this was an example of an unforeseen challenges that really pushed Mr. G. and his students to have difficult, uncomfortable conversations—ones that ultimately helped the class and teacher care more deeply for one another.

With the onset of COVID-19 and distance learning, Mr. G. has attempted to adapt "Notes to Mr. G." to a digital format, and while it has lost much of its personality through losing the written word, the core of the project remains—teacher and student connecting through writing in non-threatening, non-academic, non-evaluative ways. Clearly, the complexities of "Notes to Mr. G." as a teaching strategy and the study of it as an action research project extend far beyond what is written here, but the core concept is of value in considering ways in which teachers can live their curriculum.

Transforming understanding of electrical drawings using practical tasks

Mr. M. teaches electrical engineering at a college in an urban district in KwaZulu-Natal, South Africa. He has been teaching for seven years and he lives in the community neighboring the college. However, the majority of his students (nearly 85%) travel from outlying rural areas, using public transport, to the college. Mr. M. identifies as Asian while the vast majority of his students (nearly 85%) identify as African. Mr. M. is a dedicated teacher who genuinely cares about his students and is passionate about motivating his students to achieve good grades and find suitable employment. He finds teaching an enjoyable and rewarding experience. He is decidedly aware of the demands in the workplace for skilled and knowledgeable electrical engineers or electrical technicians to meet the growing shortage of such skills in society and globally. He feels that while his teachers and parents encouraged him to study and become an apprentice in the electrical industry, there was so much pressure on his students from parents and the community to complete their electrical engineering course quickly, achieve good grades in tests and examinations, and get a job and provide economic support to their families.

To pursue his goal of enhancing competence in interpretation of electrical drawings, Mr. M. conducted an action research project for his Bachelor of Education Honors degree called "Practical tasks to enhance interpretation and understanding of electrical drawings at a Technical Vocational Education and Training (TVET) college". His project aimed to transform his teaching strategies when teaching electrical drawings and improve students' competencies by incorporating more practical tasks in his teaching. At the beginning of the year, Mr. M. explained the rationale and purpose of the action research project to his students. Students were asked to keep a reflective journal in which they expressed the challenges they experienced in understanding and interpreting electrical drawings. The prompts for student writing on electrical drawings ranged from: "What did you enjoy about doing the practical task?", "What were the challenges you experienced?", "Do you believe that practical tasks should be done before, after or incorporated into the theory lesson?", "How did the practical task enhance your understanding of the drawing?", "To what extent are you confident to interpret electrical drawings at the workplace?", "Why do you think it is important to draw to learn or learn to draw?".

Mr. M. also observed students during practical tasks to note whether they enjoyed the practical tasks, developed requisite skills, and engaged actively. Focus group discussions were also conducted to discuss students' learning and challenges during the practical tasks. Mr. M. also shared his childhood experiences of drawings and the challenges he experienced with electrical drawings as well as some tips or hints about electrical drawings. This represented the informal process and authentic conversation between teacher and students.

The action research project afforded Mr. M. opportunities to reflect critically on his praxis, his learning as well as his students' learning—Mr. M. learned about using a new teaching strategy of incorporating practical tasks when teaching electrical drawings as students came to learn how to interpret and understand electrical drawings. Mr. M. purposefully adapted his pedagogy and the curriculum he taught based on what he learned from students' reflective journals, their dialogue and his observations and experiences. After completing his action research project, he realized that students communicated more freely during focus group discussions and shared that they enjoyed the practical tasks. He also learned that practical tasks enhanced students' understanding of electrical drawings. An important realization was that by emphasizing practical skills and tasks to enhance understanding of electrical drawings, he was able to bridge the theory and practical gap. Students shared that linking theory to practice enlightened them about electrical drawings and work opportunities. This showcased the living and learning through the curriculum of both the teacher and students.

The onset of the COVID-19 pandemic served as a catalyst to shift to online and distance teaching and learning. Mr. M. has attempted to adapt his teaching strategies to a digital design or flipped classroom. Although face-to-face teaching and learning has been relegated, online and distance teaching and learning has become the most prominent platform. Mr. M. attempts to retain the core principles of culturally relevant pedagogy and the lived curriculum through action research. It is clear that incorporating practical tasks improved understanding of electrical drawings, so Mr. M. has introduced the use of social media and Whatsapp Group Discussions. He shares videos and voice notes with his students and students share their concept maps, drawings and learning experiences as voice notes and messages on the Whatsapp Group. In this way, authentic dialogue between teacher and students continues and they can connect through non-threatening ways. Clearly, students are more open to engage through this online and distance platform as they have the requisite technological competencies. That is, action research and the shift to online and distance platforms affords both teachers and students opportunities to live their curriculum.

Discussion

It is important to re-state the idea that the cases above are not meant to portray answers, models, or best practices associated with culturally relevant pedagogy and action research. Rather, these two examples are presented in an attempt to showcase ways in which we have learned from our students, and the possibilities for action research to inform an ongoing, critical framework for teaching. Both teachers care deeply about education, their work as teachers, and their students. And, both teachers are enacting teaching strategies that have long been a part of classroom learning. The idea that both Mr. G. and Mr. M. are actively engaged in a cyclical process of planning, acting, observing, reflecting, and then replanning is what we find important in the context of action research. Both Mr. G. and Mr. M. acknowledged the cultural knowledge and prior experiences of their ethnically diverse students so that learning was more relevant and effective. It is also noteworthy that both teachers aligned their teaching not only with the principles of action research but also culturally relevant pedagogy.

"Notes to Mr. G." is a version of a classic teaching strategy—interactive journaling. The process of studying this journaling process—from the individualized design of journal covers, to the journal prompts, to student writing, to curricular connections—is an example of a teacher living the curriculum through studying a classroom project. The learning that Mr. G. was able to generate for his students and himself was exponentially expanded by his attention to the compounding, iterative influence of the journals. He was getting students to enjoy free writing while learning about them. He was also gauging his students' interests and writing abilities through his dialogue with them in the journals. And, most importantly for his objectives as a new teacher, he was building meaningful relationships with them through their written conversations. As such, Mr. G.'s action research was a tool for building community and collective learning in the classroom. While the journals may not have been a formal, summative assessment of his students' writing, "Notes to Mr. G." served a much higher purpose in the overall learning in the classroom. As a project it was an example of culturally relevant pedagogy in action. It was constantly evolving and providing opportunities for students and Mr. G. to voice opinions and perspectives about the classroom culture they were creating together. They were living the curriculum together.

Mr. M. critically reflected on his teaching praxis and transformed his teaching strategies to improve his students' understanding of electrical drawings. He revised and evolved his curriculum to include more practical tasks and activities—a standard teaching strategy—which students enjoyed and found very worthwhile. The processes Mr. M. engaged in—reflective journaling, observation of practical tasks and authentic dialogue in focus group discussions—showcased an example of a teacher living the curriculum through an action research project. Mr. M. was able to gauge the interests and practical competence of his students through observation and dialogue. This allowed Mr. M. to recognize and acknowledge the diverse personal and cultural knowledge of his students and the significance of their lived experiences. As such, the action research project allowed Mr. M. as well as his students to learn in culturally relevant ways and live the curriculum together. Mr. M. was able to get his students to enjoy electrical drawings while learning about them. And, most importantly for his aim to improve students' understanding of electrical drawings, he was constantly providing learning opportunities for his students to attain better results and equip them for the workplace. As such, Mr. M.'s action research served as a vehicle to enhance individual and collective learning in the classroom and maximize opportunities for student learning and academic success. And, through critical reflection, Mr. M. not only deepened his knowledge about his practices but also of his learning and that of his students. That is, through the action research project, Mr. M. showcased culturally relevant pedagogy, as he and his students constantly created a classroom learning culture and together lived the curriculum.

Implications

As stated earlier, the cases above are not presented to offer solutions or provide blueprints for culturally relevant pedagogy and action research. We don't believe that such solutions or blueprints exist. Rather, we portray the work of Mr. G. and Mr. M. to highlight the work of classroom teachers that we get to learn from and work alongside. Their work inspires us as teacher educators because they are enacting, reflecting upon, and continually refining their pedagogy in meaningful ways. The brief descriptions of their teaching above are incomplete and insufficient. The descriptions are our best attempts to provide a glimpse into the ways that practicing teachers are living their curriculum. Clearly, there are numerous limitations to these cases and we do not feel that the teaching and action research described above are generalizable or culturally relevant for all educators. What we do believe, is that teachers' experiences are generative, and the fluidity of their work with students is important in the context of continually creating meaningful curriculum. In this way, we feel that both Mr. G. and Mr. M. are engaged in processes that highlight the potential value of a teaching approach that combines culturally relevant pedagogy with action research.

More specifically, these case studies foreground action research as a pivotal tool to transform the lived experiences of teachers who explored their pedagogical practices in culturally diverse contexts. Furthermore, these case studies highlight that critical reflection is key to enhance teachers' understanding of culturally relevant pedagogical practices and the lived curriculum. We argue that the transformational and liberatory goals of teaching (e.g., Freire, 2000) and of action research offer resources for not only teachers but also teacher educators to engage with the challenge of social inequalities, the stark realities of which are highlighted by the global COVID-19 pandemic (e.g., Kumashiro, 2020). Action research created opportunities for teachers to critically reflect upon their pedagogy and broaden their understandings of culturally relevant pedagogy which considers not only the political but also the social dimensions that influence the lived curriculum, their pedagogy as well as their students' understanding and achievement.

As educators and scholars, the cultural contexts in which we develop our work are literally across the globe from one another (South Africa and the United States). Yet, we can see through the frameworks and the case studies presented in this article, that we have much to learn from the classroom teachers with whom we work. And, the similarities expressed through Mr. G.'s and Mr. M.'s action research projects show that there is important work to be done in this area of educational research. Namely, the connections between culturally relevant pedagogies and action research are potent when teachers apply them toward a vision of educational liberation. The truth is that many teachers are continually engaged in the process of planning, acting, observing, and reflecting—it is a core part of what we do with students. In this article, we argue that the purposeful study of this process—when combined with culturally relevant pedagogies—can enhance teacher and student learning for social transformation. In this way, we feel that it is important to continue to study ways in which teachers are living the curriculum.

Glossary

GCSE external examinations taken by 16 year olds in England after two years of teaching

Key Stage 3 part of the National Curriculum directed at 11–14 year olds

Ofsted the office for standards in education, inspecting services providing education and care

National Strategies programmes aimed to improve the quality of learning and teaching in schools in England. First introduced in 1998 they formed a key part of the government learning priorities

PISA Program for International Student Assessment (PISA), a worldwide study by OECD intended to evaluate educational systems by testing 15 year olds on maths, science and reading; Schools History Project set up in 1972 to undertake a radical re-think of the purpose and nature of school history

TIMMS part of a history of international comparative assessments in mathematics and science conducted by the International Association for the Evaluation of Educational Achievement

Traditionally, writing and research about curriculum reform, particularly in the case of a history National Curriculum, has tended to focus on policy documentation (Phillips, 1998; Guyver, 2012), which has led to some assumptions of direct translation between policy text and classroom practice. However, in recent years there has been a move to consider the approach teachers have taken to implementing or “enacting” curriculum reform (Ball et al., 2012). With government focus tending toward large-scale assessment data such as PISA and TIMMS, it is essential to explore the corollary and give voice to individual teachers’ experience of curriculum reform. Research with teachers can elicit personal experience of changes and continuities within the curriculum, revealing the complex network of agents teachers respond to when making changes to choice of substantive content or pedagogy. While there have been generic studies of class teachers (Priestly et al., 2015; Perryman, 2006), there is a need for subject-specificity in such research. Experiences of teaching “core” curriculum subjects such as English and maths have received some attention (Gibbons, 2017; Perryman et al., 2011), but there has been far less focus on the teachers of “foundation” curriculum subjects, for example, history. As Counsell (2000, p. 61) has argued, to “decide what history is to be taught, at school, regional, or national level, is to exercise phenomenal power.” Understanding the factors that underpin history teachers’ curricular decision making is therefore crucial if society is to reap the benefits of a relevant and rigorous history curriculum.

This article therefore sets my own in-depth research with history teachers in England within a context of other research, some more recent, some with larger data sets and some from comparative countries. First, a background to the National Curriculum in England is provided, specifically the changing details of the History National Curriculum. Second, temporally and geographically broader literature on history teachers and the history curriculum is explored to set a context. Third, a summary is given of the conclusions of my own research, exploring the lived experience of curriculum of thirteen veteran history teachers over a period of 25 years. The aim is to provide conclusions on what we can understand about history teachers’ lived experience of curriculum and how this knowledge needs to be shared in order to influence policy, practice and further research.

The history National Curriculum in England

The National Curriculum for England was first introduced in 1991 as a result of the 1988 Education Reform Act. It was initially underpinned by a focus on ten specified curriculum subjects, to be taught throughout the 5–16 age range. The National Curriculum

has been revised four times since 1991 (in 1994, 2000, 2008 and 2014), each time (until 2014) increasing flexibility and freedom, with history teachers in particular given less detailed prescription and more choice around substantive content. With the Labor landslide victory in 1997, education was declared a priority through the policy of "raising standards" (see Ball, 2008), and a series of National Strategies were introduced to achieve this aim. These initiatives, applicable across all curriculum subjects, gave an emphasis to "assessment for learning", learning objectives and student activities and came alongside significant funding to encourage dissemination and implementation. Concurrently, this period saw a gradual but significant increase in accountability measures. League tables were introduced in 1992, initially to compare success in the national GCSE examinations for 16 year olds. Ofsted, an inspection body for schools, was introduced the same year and moved over the next two decades from carrying out subject-specific inspections to a focus on progress data and school evaluation. This led to school leaders to needing evidence of progress for all children across the 11–16 age range, resulting in tight regimes of classroom observations, learning walks and data drops in many schools. It is against this backdrop of acute accountability pressures that teachers have instigated curriculum reform over the last 30 years in English schools. The particular experience of history teachers reveals the pressures on a subject where students could opt to discontinue the subject from the age of 14, concentrating on other curriculum subjects for the two years of GCSE preparation. This resulted in the 11–14 (Key Stage 3) curriculum in England becoming something of a marketplace, with subject teachers competing to recruit students to study past the age of 14 (Harris and Haydn, 2012). This in itself had a significant impact on the curricular choices of many history teachers. Besides this competition for students, the backdrop of accountability measures led to increasing pressure to start preparing students for the GCSE examination from a younger age.

In order to understand the position and experiences of history teachers across this period, it is necessary to give a brief history of the history curriculum in England. The original National Curriculum documentation for history, taught from 1991, was a merger between two competing approaches to the subject. There was notable influence from the "great tradition"; didactic teaching of a mainly British, political history to mainly passive pupils (Husbands et al., 2003) but the inclusion of evidential understanding demonstrated the influence of the Schools Council Project 13–16 (later Schools History Project [SHP]). It has been argued that in moving toward SHP, history teaching developed from a "technical act for conveying knowledge" to a "cultural act that taught students about warrant, about the nature of understanding and about their own role in making historical knowledge" (Stearns et al., 2000, p. 3). These quite different approaches to the nature and purpose of school history led to some debate during the construction of the National Curriculum. The initial version of the documentation was problematic due to "the overwhelmingly overloaded content" and "the difficulties of the assessment stages and targets" (Cannadine et al., 2011, p. 199). Eight detailed study units were prescribed, spanning over 2000 years of history. This content was to be assessed through three attainment targets covering knowledge, understanding, interpretations and sources. Theoretically, this put historical processes at the center of the history National Curriculum. However, the detail in prescribed content and assessment proved complex in practice. Foster, writing soon after about his experience as head of humanities during the introduction of the National Curriculum, suggested the proposals were "too prescriptive, detailed and unrealistic" (Foster, 1994, p. 376). In 1993 Lord Dearing was commissioned to simplify the demands of the National Curriculum across all subjects, including history.

As a result of this review, the History Program of Study for the National Curriculum was substantially slimmed down. Nine Level Descriptors were introduced to standardize assessment of progression across the age range from 5 to 14. This document also saw the move to five "Key Elements" which summarized the second-order concepts and processes underlying the teaching and learning of history, emphasizing a disciplinary framework. Further reforms to the Program of Study in 2000 and 2008 made few distinct changes, but it became less prescribed and more flexible. The 2008 document had a particular focus on "cross-curricular" approaches. Schools were encouraged to combine subjects, to develop thematic approaches and to organize their timetables in novel ways (Kitson et al., 2011).

By 2010 though, with New Labor losing power to a Conservative-led coalition government, school history was in a weak curriculum position. Ofsted argued that it was a very well-taught subject (OFSTED, 2011). However, the same report indicated that history was being marginalized in fourteen of the fifty-eight secondary schools visited between 2008 and 2010. A parallel report from the Historical Association led to similar findings, reporting increased teaching by non-specialists in the early years of secondary school, a reduction in the time allocated to the subject and restrictions on which pupils were allowed to take history beyond the age of 14 (Burn and Harris, 2011). The authors suggested, "Division between those encouraged and enabled to study history and those denied such expertise or deterred from continuing with the subject is based on socio-economic factors" (p. 1). It was at this point that exploring history teachers' lived experience of curriculum appeared vital, to understand the disconnect between the flexibility of official curriculum policy and the reality of teachers' experience in history classrooms.

History teachers' experience of curriculum since 2010

In 2010 a Conservative/Liberal Democrat coalition came to power in the United Kingdom. This led to reforms across the curriculum, with new specifications for external history examinations at 16 and 18 introduced in 2016 and 2015 and a new National Curriculum Program of Study introduced in 2013. While several new external examination specifications (for GCSE examined at 16 and A level examined at 18) and programmes of study (for 11–14 year olds) since 2010 would suggest great opportunity for curriculum reform, research has shown that accountability measures have tended to dominate history teachers' lived experience of curriculum in English schools. The Historical Association, the professional subject association for history teachers in England, has carried out annual online surveys of its members since 2009. Several reports and papers have used this data to draw conclusions about the current state of history education (Burn et al., 2018 see for example, Harris and Burn, 2016; Harris et al., 2019), but

conclusions can also be drawn concerning teachers' experience of the curriculum and particular curriculum reforms. For example, data collected through over 1100 survey responses between 2015 and 2017 showed that history teachers' decision making tended to be influenced by performative demands. Accountability measures dominated history teachers' thinking as they tried to implement curriculum reforms for external examinations at 18 and 16 (Harris and Graham, 2019). Teachers' attitudes, beliefs and values were explored alongside opportunities for teacher agency. Marketization of the curriculum and league table pressures for constant progression were found to influence what history teachers chose to do in non-examined phases of the curriculum, forcing teachers to choose between "educational outcomes and educational values" in the design of their Key Stage 3 curriculum. Teachers' agency when designing a curriculum was therefore found to be diminished.

There is however evidence of history teachers in England being passionate and informed about what should be within National Curriculum documentation and willing to fight for less prescription and more responsibility for design and choice at school level. Controversy surrounded the 2013 reform of the History National Curriculum where a draft version was published prescribing a long list of topics, events and individuals to be taught chronologically that all students would be expected to the study. Nearly 550 teachers responded to the Historical Association annual survey in 2013, two-thirds sharing written comments concerning this draft curriculum. The data provided a unique insight into history teachers' understanding of the curriculum and disciplinary history (Harris and Burn, 2016). Research into these comments found teachers communicating a variety of concerns, from the relevance of the proposed content to an over-emphasis on political history to the geographical spread (with an inappropriate balance between British history and the history of other countries and cultures). Over 95% of respondents found the amount of prescribed content inappropriate, showing a desire among English history teachers to take responsibility at school level for many decisions around substantive content. Following the negative reaction to the proposed curriculum, significant changes were made before the new version of the Program of Study was published (See <https://www.gov.uk/government/publications/national-curriculum-in-england-history-programmes-of-study>). However Harris and Burn (2016) were able to use the teachers' comments to gain an insight into their understanding of curriculum content. It was clear that these teachers saw history as being "more than a body of knowledge" (p. 537). Beyond that there was some desire from teachers for "relevant and interesting" material (p. 539) and an emphasis on a disciplinary approach. The authors concluded that "there remain powerful tensions for teachers caught between trying to develop young people's understanding of history, while seeking to serve the more generic aims of school education." (p. 539). This research and the reaction of history teachers to proposed changes to the history curriculum show the level to which teachers are engaged with the document, but also the extent to which they bring their views about the substantive and disciplinary history to their planning and enactment of the curriculum. This is far from a passive act. Not only is the document mediated, but engaged teachers are able to push back, through subject associations as lobbying bodies to reject extreme curriculum reforms. The authors noted the findings from the Historical Association survey formed part of the negative reaction to the proposals, resulting in significant changes being made to the final version of the National Curriculum.

Contrasts from other countries

While history teachers in England seem to struggle, at times, for curricular autonomy, it is interesting to contrast the experience of history teachers in other countries where there appears to be more teacher agency in curriculum planning. In Scotland, for example, teachers have an unusual degree of curriculum autonomy specifying no mandatory historical content in its social studies curriculum. A detailed piece of research with 21 Scottish history teachers explored how this curricular autonomy was used (Smith, 2019), finding that without access to theoretical debates about the nature of historical knowledge, teachers tended to fall back on instrumental justifications for content selection. This tended to lead to an extremely narrow and fragmented syllabus based upon pupil preference and teacher interests. Priestly et al. (2015) have suggested a need to increase teachers' agency through better access to research literature and greater collaborative working. Smith adds to this in demanding a professional conversation about the purpose of history.

Similar research has been carried out in New Zealand where the government also decided to move away from prescribing topics in a history curriculum. Ormond examined the complex nature of teachers' new role and responsibility in this context and found curriculum achievement objectives and national assessment placed significant constraint upon teachers' selection of historical knowledge (Ormond, 2017). She stressed that local curriculum making placed "a heavy burden of responsibility" upon teachers (p. 599). Further, Ormond (2019) found that the need for assessments to tightly fit the wording of national standards has limited flexibility around selection of historical content. Therefore in New Zealand, as in Scotland, high levels of teacher autonomy on paper through an open curriculum have not necessarily led to successful teacher agency and rigorously devised history curriculums at local level due to other accountability pressures in New Zealand and a perceived lack of subject-specific professional development in Scotland.

There is limited literature that explores the teachers' perspective on how history teaching has changed over time. Cuban's (2016) work on history teaching in America, however, has similarities to the research discussed here as it considers changes in history teaching over 50 years from the 1960s. Cuban chose a semi-autobiographical approach, detailing his own experience of teaching in two schools at the beginning of his career and then returning to those schools five decades later. He found considerable continuities in history teaching, estimating that only a quarter of schools were using what he termed the "New History" that prioritized the place of evidential work in the history classroom. These three examples show that changes in selection of content in the history classroom and approaches to how history is taught are complex and affected by many different factors beyond curriculum documentation, such as teacher agency, accountability measures and marketization within schools.

Methodology

This research sought to explore how teachers perceived, experienced and enacted curriculum and policy. Accessing teachers' experiences of curriculum is not a simple task as frequent changes to policy documents, examination specifications and local contexts impact the decisions teachers make concerning the way curriculum is enacted in the classroom. It was decided to explore such changes retrospectively by talking to history teachers who had been in the classroom for twenty-five years or more. The intention was to know more about changes in how the curriculum was enacted over time and the impact other agents had on the curriculum decisions made by teachers. Twenty in-depth, semi-structured interviews were carried out with thirteen experienced history teachers between 2011 and 2016, using an oral history approach to explore change over time.

As a "way of knowing," there are inevitable limitations to the use of oral history; potential problems associated with mis-memory, accuracy and selection. One problem in the study of memory is that any narrative is not necessarily linear, but sporadic and segregated, encroaching on history to differing degrees at different points in the past. Part of this problem arises from the issue of how to access and study memory, whether at an individual or collective level. In *History as an Art of Memory*, Hutton (1993) argued that memory is an internal activity of the living mind that can never be recovered. This poses a challenge for the historian who is limited to studying the ways in which memory manifests itself outside of the mind. Halbwachs (cited in Hutton, 1993) believed the historians' first task was to keep memory honest, "to remedy its distortions of the past by comparing its suspect claims to those based on documented historical evidence" (p. xxiv). By setting oral history accounts against a contextual backdrop gathered from other sources a justified, valid account of the past can emerge. As Cunningham (2006) put it, "documents and personal memory together can shed new light on important themes" (p. 16).

A distinction is also worth making here between life history and oral history. Although the teachers were asked to complete a timeline before the interview that included teacher education, changes in position etc., the open-ended style of questioning gave the teachers room to select the changes in history teaching that were important to them. Gardner (2003) has made a distinction between life history and oral history. While both may use life stories elicited through interview, arguing that oral history emerges when individual memories are probed "for more precise, detailed or verifiable information about the past" (p. 179). In choosing to explore a historical concept such as change and with an aim to enrich the existing historical record, it was decided to use a specifically oral history approach, seeking witness of events and changes that took place in the classroom, rather than a life history approach which might have focused more on the broader lives of participants themselves (Gardner, 2010). This research sought to provide and understand a story of change in history teaching across 25 years. It looked to the stories and experiences of individual history teachers for evidence of that change.

Interviews were transcribed, coded and set against secondary literature and contemporary policy documentation. The teachers involved in the study taught history in the secondary classroom from 1985 to 2011, with most teaching across the whole period. This led to a very particular group of teachers, only a small minority of whom had moved into senior leadership positions, but all of whom were passionate about their subject. Oral history interviews rarely provide a neat, complete account of chronological events. In this study, for example, teachers proved more familiar with the detail of school and classroom experience than with the minutiae of policy or curriculum documentation. The fragmentary nature of interview evidence, coupled with the potential problems of memory suggested a need to set a historical backdrop from alternative sources. This provided a chronological and contextual structure within which to frame the evidence of participants.

The findings provided evidence of a dedicated group of teachers who experienced and enacted sweeping curriculum and policy changes across the course of their careers. Their memories of the period add a rich layer of detail and an affective dimension to the existing literature in this area. Several research questions underpinned the study:

- How did history teachers perceive, experience and enact curriculum and policy changes 1985–2011?
- How did history teaching in English secondary schools change between 1985 and 2011?
- What agents acted on teachers to effect change over this period?

The findings shared in this article will focus on the teachers' lived experience of curriculum reform.

English history teachers' experience of curriculum reform since 1985

There was a dramatic shift in the nature and place of knowledge in the history classroom from the 1980s onwards. Various of the teachers described a traditional, rather didactic approach to teaching history in the early 1980s. Richard described a conversation with his mentor during teaching practice:

I said, look I'm sorry Mr D, what do you want me to do with your class? He said, "well" he said, "I've got up to page 37, page 38 looks good to me, does it to you?" And that was it. That was all I got.

Simon described similar textbook-based practice:

I can certainly remember when I first came into teaching, rows of very miserable-looking children, with a textbook and a pen, and, and an exercise book, with, well, in some cases dictation still going on, and I think that probably, that was probably the end of that era.

Many teachers followed a pragmatic, "dual practice" approach early in this period, including "new history" principles of source analysis and evaluation alongside more traditional approaches. Simon described his approach:

There'd be a balance between chalk and talk and question and answer and the things that go on all the time and the sort of sources-based, skills-based, evidence-based stuff that was quite popular at the time.

It was the introduction of the national, uniform GCSE examination from 1986 that meant such traditional approaches were no longer enough in the history classroom. With the introduction of this new qualification, replacing the more traditional O-level examination, it was no longer possible to teach history to 16 without teaching pupils to consider the provisional nature of historical knowledge. As Edward put it:

the source-based, evidence-based work was much more important than it was with the O-level, I mean the O-level that I taught was really about essay skills ...

Several of the teachers in this study acknowledged a necessary shift in their epistemology at this time. However, the research shows that such changes were neither linear nor necessarily embraced by all teachers. Twenty years after the National Curriculum was introduced, the specific disciplinary language of the History Program of Study was not at the forefront of these teachers' discourse about their practice. The National Curriculum can therefore be seen to have only partial responsibility for this shift in practice, with the shifting demands of external, national assessment in the shape of the GCSE examination acting as more of a catalyst for change within an era of accountability measures.

There was evidence of a shift in all the teachers in this study from "authentic professionals," concerned with the development of substantive historical knowledge in the 1980s to more "technical professionals" with a rather different discourse by the 2000s. According to Ball et al. (2012), where the "technical professional" is created by the policy artifacts of data collection, analysis and measurement (p. 5) the "authentic professional" is "required to bring judgment, originality and passion to bear upon the policy process" (p. 94). The intensified focus on examination results, particularly in the 2000s, led to an emphasis on technical knowledge or how to succeed in examinations and progress through National Curriculum "Levels" of assessment that in several cases displaced an earlier substantive focus. Teachers felt increasing pressure to teach to assessments. Alison compared the shift in her teaching from the early 1990s to twenty years later:

It used to be short questions, short answers and essays. And now it's enquiry-based, it is source-based. We gear our questions, even for Year 7 [5 years before the examination] very much along with lines of GCSE-type questions so that they get used to that formula The bigger influences were the exam boards, and what they required obviously because you know, you've got to get kids used in Year 7 to what's likely to come their way in Years 10, 11, 12 and 13.

Richard gave an honest account of the technical knowledge he needed to share with his pupils:

Certainly, at both A-level and GCSE I tell them exactly how to do it. My GCSE revision session tomorrow, it won't be on how to revise Nazi Germany, it will be on how to do question one. This is what they're asking for, this is how to answer it and make sure you do that. And at A-level even more so It's basically a game that you have to play and you've got to know the rules of the game.

For some teachers, there was a constant fear of Ofsted, placing constraints on the "authentic professional." There was a distinctive difference in the discourse teachers used to describe teaching in the 1980s and teaching in the 2000s. The assessment-focused language of the technical history teacher appears to have been particularly a product of the 21st century. Stories from these interviews about teaching in the 1980s were full of descriptions of substantive content or approaches to teaching such as resource boxes and trips. Laura and Alison were excited about the possibilities of local history; Patrick talked of the theme of women's history running through his schemes of work; William looked for opportunities to teach African history. Noticeably, there was virtually no mention of assessment outside the formal examinations of O-level and CSE. Descriptions of the 2000s, particularly the later part of the decade, however, were dominated by talk of assessment. This significant change in discourse suggests a change in priorities for the history teachers interviewed. For the majority of participants, the experience of teaching history had changed from a passionate exposition and sharing of the substantive content they valued to a vehicle for examination success. This was not a result of the National Curriculum or changes in the National Curriculum, but a direct result of a need for evidence of "progression" to meet the dual performative demands of league tables and Ofsted.

One key finding from this research was that different groups of teachers could be seen to respond to the same curriculum in different ways. While some teachers feared the level of detail in the initial Program of Study, a small minority minimized the impact of the National Curriculum and focused only on changes in assessment. A third group had their own pre-existing professional

agenda to realize and feared the National Curriculum would impede those personal goals. For each of these groups, the process of accommodation was different. Exploring detailed interviews with veteran history teachers enabled a move away from teachers being treated as a homogenous body in the research literature. One small subset of the teachers interviewed appeared to be able to resist or mediate some of the more performative policies around assessment. Context may have had a large role to play (Priestly et al., 2015), but each of these teachers spoke favorably about their early career experiences, sharing in particular detailed discussion and debate with colleagues around the subject of history and approaches to history. As Patrick described it:

I do remember we had quite profound philosophical debates between the deputy head, a real SHP man, who insisted it had to be pure, and myself and the head of department saying no, we've got to edit them [written sources], we've got to simplify them, we've got to make them accessible, so that was quite interesting.

It is quite possible that such opportunities to articulate and define their approach to the subject early in their careers had a long-term impact on their approach to teaching and the enactment of policy. This was a small, but convincing group of teachers. Smith (2017) has written of an "epistemological introspection" (p. 325) that seems to have provided these teachers with a rather more resilient, resistive approach to enacting policy. These teachers were noticeably more articulate about history as a discipline in comparison with many other teachers in the sample.

This research provided an insight into teacher agency, particularly how the teachers believed that agency had changed over time. One fundamental change in the experience of teachers interviewed was the reduction of autonomy that all of them experienced and chose to talk about. In 1985 teachers could choose the content that they wanted to teach across the time and space of history and select their own pedagogical and epistemological approach to teaching the subject. This autonomy was gradually eroded, first by the introduction of the GCSE examination and the National Curriculum, but to a far greater extent by the government policy of National Strategies and the surveillance and data pressures introduced alongside them in the decade following 2000. Not being able to choose how a lesson was taught, for how long the teacher could talk or whether to write lesson objectives on the board was seen by the teachers interviewed as a far greater intrusion into teacher autonomy than GCSE and National Curriculum interventions. Allan described his experience:

Perhaps it was just a new headteacher taking over and interpreting what Ofsted wanted in a more draconian way which led to half-termly observations for every teacher ... because they had a tick-list of what they were looking for it discouraged innovations.

The schedule Allan described would have seen all teachers in the school having formal lesson observations six times over the course of a year. This was much more a surveillance, performative culture than had previously existed in the school. When Allan was asked whether the "tick-list" he mentioned was subject-related, he responded:

They were generic, very much generic that teachers should not be at the front of the class doing whole class teaching for more than about 15% of the lesson time [So that, I imagine is quite a change from your previous approach?] Absolutely, absolutely and that's not really my style. I like to be at the front and leading discussions—breaking off and going into discussion groups for a few minutes and then coming back. [So did you take that on board, that advice, or did you mediate it in some way?] I tried to mediate it, but what I did do, I was observed by the head teacher and I exceeded the 15% quota and was marked down.

While "authentic" examples of autonomy, agency and mediation of policy were present in the evidence of teachers interviewed for this study, such examples were more apparent where teachers had strong disciplinary knowledge and professional confidence alongside working in departments or schools which offered pedagogical freedom. What happened in the history classroom over this period became increasingly prescribed in terms of content, pedagogy, assessment and the status of the subject on the curriculum. Pressure to constantly improve examination results led to a climate of fear in some history departments. While on paper the National Curriculum at this point, was open and free for teacher interpretation, in practice teaching approaches were limited by the generic demands of senior leadership teams, under the influence of the National Strategies and the "raising standards" agenda. Some history teachers and departments were seriously affected, feeling they were compromised in the way they taught the subject due to the demands of senior managers, exam boards and Ofsted. While some teachers saw the need to put into place every initiative and policy according to the letter, others felt more able to resist and mediate the way they enacted the policy, perhaps putting the disciplinary and learning needs of students before the need to conform to performative initiatives from senior leader.

This research approach allows some analysis of the impact of the National Curriculum and subsequent changes to Programmes of Study on the practice of history teachers. Evidence from these teachers suggests the main driving force behind changes in history teaching was the pressure for success in external assessment rather than the Programmes of Study of the National Curriculum. The vocabulary of GCSE mark schemes and National Curriculum Level Descriptors were far more prominent in the language used by teachers than the language of the "Key Concepts and Processes" or "Key Elements" that have made up the disciplinary focus of the National Curriculum. These teachers' experiences of the National Curriculum seem to focus on substantive content, rather than the

minutiae of changes in the various disciplinary "Key Elements" (see Counsell, 2011). This, therefore, suggests many teachers needed more than curriculum documentation in order to effectively teach the disciplinary structures explicit within the National Curriculum Program of Study.

Driving forces in changing approaches to history teaching can be seen in changing resources, particularly textbooks and technology. These were high on the priority list for teachers interviewed to talk about. However such tools do not seem to have promoted changed approaches, but rather emphasized existing approaches. Simon and Allan gave examples of particular textbooks supporting their development of overarching enquiry questions, which was critical in their development as history teachers, but this move did not happen in isolation. The support of teacher networks and conversations with other professionals played a significant role in professional development. Resources were rarely enough to provoke change unless they came as part of a package of professional development. All the teachers interviewed spoke with one voice about the decline in opportunities for subject-specific development in comparison to their early-career experiences. Allan, for example, described the professional development opportunities at the inception of the National Curriculum in the early 1990s:

one of the things we used to do was to run regular three-day courses. Often with between fifty and a hundred history teachers over 3 days that you could really immerse yourself in developing curriculum materials and working together. That's a big loss I think. That's a big loss.

From the late 1990s onwards, opportunities for subject-specific development seem to have become more limited, with generic development opportunities linked to National Strategies more widely available internally to schools. There were still opportunities for professional development through examination boards, but those teachers involved were adamant that opportunities for discussion had become limited at such events. Teachers welcomed the opportunity to work as mentors for initial teacher education courses. However, diminishing quotas for history teachers and the development of school-led teacher education programmes also limited the opportunity to work with universities and other subject-specific teachers in this way.

Conclusions

There are therefore benefits to this way of knowing or exploring teachers' lived experience of curriculum. The in-depth interviews with a small number of very experienced subject teachers provided an insight into significant change over a substantial period of time. The use of a semi-structured interview technique allowed teachers to select and talk about the curriculum opportunities and limitations that they felt passionate about, and this selection was illuminating in itself, with an obvious move from talking about substantive knowledge decisions early in their careers, to assessment dominating descriptions of more recent years. Through this in-depth approach, different groups of teachers could be identified, analyzed and followed across the three decades. Responses to National Curriculum measures from a central government could be compared to responses from senior leadership initiatives within schools and teachers were able to share their emotions and anecdotes, providing a rich and insightful level of detail to a well-known over-arching narrative. There were limitations to this methodological approach; whether such a small number of teachers could represent a national picture of experience; whether taking veteran teachers led to a certain slant on experiences of the National Curriculum that might not have been represented among younger teachers.

As recruitment and, particularly, retention of teachers remains a serious issue in England and beyond, it is crucial to find ways to listen to teachers' experiences. The teachers described above were uniformly passionate about the subject of history and the opportunities it could provide for their students. However, it is rare that they were given the opportunity to share that passion beyond the school walls. Several of the teachers in this study commented on what a cathartic and unusual experience the interview had been. They weren't used to being listened to or being offered a voice or for their experiences to be valued. If the problems of teacher retention in schools are to be addressed, then offering a voice to experienced, older teachers through research or otherwise is crucial. The nostalgia these teachers offered concerning local networks of history teachers may suggest one possible way forward; certainly, the valuing of continued subject-specific development for history teachers beyond of that offered by examination boards would be one recommendation for school senior management teams. The teachers within this research spoke powerfully about their early years in the profession and it is clear that new teachers need subject-specific nurturing at that stage of their career and beyond so that they are able to mediate any more generic government policies through a subject-specific and curricular lens. The opportunities teachers are given to articulate and define their understandings of the subject within subject-specific groupings in the earliest years of their career could prove fundamental to the way they are able to teach, lead and enact policy long into the future. This in turn could provide for a more engaged, contented and resilient long-term teacher workforce, that has an authentic approach to enacting curriculum policy.

Fundamentally, however, it is crucial to recognize and further explore the disconnect that often exists between the official, written curriculum and teachers' lived experience of curriculum in the classroom. If teachers are pulled in two directions by different government policies, in this case the detail of curriculum documentation and the accountability of the performative system, then this needs to be acknowledged. As this article is written, the history curriculum in England is in the media due to a perceived lack of coverage of Black British history in the classroom within the context of the Black Lives Matter movement (Leach et al., 2020). It is crucial that a diverse history is taught within our classrooms, and this is often the case as articles in the professional journal of the Historical Association, *Teaching History*, regularly show (Priggs, 2020; Mohamud and Whitburn, 2019; Lyndon, 2006). As this

research has shown, teachers often have the agency to go beyond the written curriculum and make choices based on their professional and disciplinary knowledge of the subject. The taught curriculum, teachers lived experience of curriculum, however, is so much more than the official written documentation of curriculum. In order to ensure that students can be taught the diverse histories that they deserve and need, the performative constraints acting on curriculum choices need to be acknowledged and then removed. If there are classrooms where teachers are not teaching Black British history, this is not the result of detail (or lack of) in a written curriculum, but the need for career-long subject-specific development, examination specifications that encourage innovation and professional conversations that challenge the status quo.

Curriculum's multiplicities as participatory modes of interaction

This article grapples with the needed participatory stance and associated lived understandings to embody curricular enactment as individual/collective meaning-making. In doing so, the article confronts what such enactment orients toward and why. A theorizing language of practice is found through the thinking of American Pragmatist, John Dewey, in conversation with contemporary curriculum theorists' reinterpretations and found kinships with Indigenous wisdom traditions. First, the lived terms of curricular enactment's multiplicities are foregrounded and then associated ways of being and habits of practice are explicated. Curriculum's multiplicities are illuminated through participatory modes of interaction, revealing stories of humane becoming as integral within traversing curricular terrain that attends to meanings-in-the-making. Worldwide, inequities have been foregrounded over this last year—made much more visible and tangible through local and global happenings' disregard for humane becoming. Capacities to foster and sustain diverse learner/learning spaces and invest in meaning-making that is genuinely inclusive, attentive to equity, are core professional skills for educators to embody. Students need to gain these habits and practices too. Communities need to, as well. The article positions readers to reflect on the seriousness of what has happened in the name of education and the lived consequences of ignoring curricular enactment's multiplicities manifesting through humane becoming. A shared commitment to the powers and possibilities of curricular enactments' multiplicities is generated.

Introduction: slippery slopes of reconceptualized curriculum

Meaning-making is elemental to being human. Human beings are meaning-makers—adapting, changing, and building understandings through knowledge-making discourses (e.g., Bruner, 1990; Dewey, 1934; Dissanayake, 2015; Duckworth, 2006; Greene, 1984; Scardamalia, 2017). Curricular situations that bring students, educators, community members together from across disciplines and interests to co-create learning experiences, invest in this elemental and formative nature of knowledge. Harkening back to the Latin root of *curriculum*, co-creating is at the heart of *currere*, reconceptualizing curriculum as a moving sense-making journey. Such characterization draws on the work of reconceptualists over the last five decades, and their re-envisioning efforts within the field of curriculum studies (Doll, 2017; Malewski, 2009; Pinar, 1975; Pinar and Grumet, 2015; Pinar et al., 1995). In 1978, Pinar, reflecting on the use of the term *reconceptualist* called it a “slippery” notion (p. 205); slippery, because the lived terms are interdependent with curricular enactment that embraces the contingencies of multiplicities encountered through knowledge-making discourses. It is such multiplicities that Pinar (2015) foregrounds in his notion of “complicated curricular conversations” engaging participants in ongoing “multi-referenced” conversations (p. 11). The complicated curricular conversations that ensue encourage the reconstruction of participants' lived worlds through “reanimation of the material they study” (Pinar, 2010, p. 5). But, such reanimation is limited and thwarted if preoccupied with predetermined evaluative educational measures and expectations. Pinar (2010) explains how it is persistent institutional neglect of the intellectual quality and character of the curriculum that holds lived consequences that orient curricular enactment very differently. For example:

- valuing singular perspectives and discounting varied histories, traditions, and narratives of experience, orients toward knowledge transmission;
- following set learning sequences and regulated learning paces, resulting in generic learning products that discount more fluid purposeful learning experiences through divergent learning processes and varied learning products, orients toward preconceived ways to learn particular content; and

- masking differences as catalysts in coming to know self and others, limiting, thwarting or losing opportunities to learn with and through others' experiences, orients toward prefigured ways of being and doing.

Thus, the slippery slopes of reconceptualized curriculum foreground the primacy of multiplicities as always present within all situations. But, concomitantly, needing to be valued as productive givens, catalytic within teaching/learning experiences of all kinds. Recently, [Pinar \(2022\)](#), reflecting on the reconceptualization of the field of curriculum studies, explicates how these complicated conversations traverse “across generations, reactivating the past to find the future, an ongoing dialogical encounter in service to conscientization, located in, animated by—as it supersedes—the historical moment and the individual lives of those submerged in it.” And, such an attentive gaze while traversing the curricular terrain entails locating and navigating these multiplicities as the needed matters or resources shaping all inquiry as it unfolds. It is this ongoing attention to process that continues to be persistently misunderstood within educational institutions and communities worldwide. When the traversing activities themselves are reduced solely to a predetermined approach, strategy, technique, or method, meaning-making is not occasioned nor the associated learning opportunities and powers. Rather, the activities can thwart and stultify multiplicities. Again, and again, such misunderstanding disregards what [Dewey \(1910\)](#) terms the presence and power of human beings' innate resources of curiosity inciting meaning-making suggestions and order-making, as habitual dispositions catalytic within learning of all kinds.

Lived terms of curricular enactment's embrace of multiplicities

Curricular enactment, unfolding as moving sense-making journeys, positions educators, students, and all involved as active participants, residing and contributing within such movement of thinking. Residing and contributing accordingly, entails dwelling at the conjuncture of multiplicities of meanings that educators, students, and others bring, encounter, and negotiate. It is the found nuances, intersectionality, and arising possibilities that such dwelling acknowledges ([Aoki, 2005](#); [Hansen, 2011](#); [Schubert, 1986](#)). Most importantly, these multiplicities are understood as deserving of everyone's attention. And, it is this capacity for greater awareness or sensitivity to the multiplicities at play that educators alongside their students must awaken and cultivate to concomitantly see and act within curricular enactment to further learners and learning. [Dewey \(1929\)](#) explains that traversing such moving terrain, marks a rhythmic movement “preserving and propagating a creative attitude” (p. 132).

It is through releasing of creativity as an attitude within meaning making of all kinds, that [Dewey \(1929\)](#) claims genuine inquiry is authorized, positioning all involved to enter as creators, makers of meaning (p. 132). Many contemporary theorists concur reiterating how entering into curriculum-making as an individual/collective co-creating undertaking insists on room to draw attention to the many relational complexities ([Aoki, 2005](#); [Biesta, 2013](#); [Bingham and Sidorkin, 2004](#); [Greene, 2000](#); [Macintyre Latta, 2013](#); [Noddings, 1984](#); [Seidel and Jardine, 2016](#); [Stengel, 2016](#); [Thayer-Bacon, 2004](#); [Wearing et al., 2020](#)). And, it is the deliberative engagement with these relationships that demarcates such sense-making terrain concerned with caring interactions, deliberations, debates, and discernments made within process. A vitality takes life that gives expression to the individual/collective movement that unfolds. [Dewey \(1934\)](#) describes the sense-making movement as being “carried out beyond ourselves to find ourselves” (p. 195). It seems such liberating movement is the heart, fueling and vivifying multiplicities vitality. Pursuing the lived terms of such vitality, [Aoki \(1991\)](#) confronts the static interpretations of many terms in education. He states, “Time-honored words, curriculum and pedagogy, with their frozen meanings need to be placed into turbulence, alert to the multiplicity of meanings and, as well, the legitimation and delegitimation of certain of these meanings” (p. ii). And, it is such unsettling of terms that he calls “inspired” (2005, pp. 357–365). Through multiplicity of meanings, inspired turbulence discloses telling learner/learning significances, instilling the needed liberating agency. It is this movement insisting that all involved situate themselves in the world again and again that forms the task of co-curricular-making, orienting toward greater individual and collective self-understandings. And, it is the vitality of such liberating terrain that participants alongside policies and practices, keep betraying and fearing within curricular enactment.

Grounded within co-curricular-making's concrete engagement, attention is given to the moving curricular terrain of embracing multiplicities. Associated ways of being and habits of practice emerge, giving expression to pedagogical makings which facilitate this movement. And, it is these participatory modes of being that have been, and continue to be, repeatedly circumvented. Curriculum severed from teaching and learning denies the needed modes of being and habits of practice that insist on educators, students, and communities traversing together the curricular terrain encountered, orienting toward individual/collective growth and well-being. Seeking greater physicality and materiality embodied within the very nature of humanity's being-ness, insists on personal investment within curricular enactment. It is only within the ongoing confronting and challenging of self-understandings that the contextual conditions and criteria to foster and nurture the lived curricular consequences emerge as productive for learners/learning and teachers/teaching. So, what are these needed modes of being and associated habits of practice? What do they orient toward and orient away from? What is at stake for liberating curriculum as a medium for sense-making, inspiring participatory modes and habits toward learning/living well in the world with others? Curriculum's multiplicities as openings offering ways of being and proceeding, prompt knowledge-building discourses. The associated co-curricular-making enters into a shared ethical commitment to openness with willingness to challenge values, assumptions and beliefs, alongside boldness to grapple with difficult and complex issues. Such attentiveness and investment in process, from within process itself, are integral. These knowledge-building discourses and associated meaning-making habits insist on what [Bal \(2002\)](#) terms, “traveling concepts”; operative processes informing how knowledge is acquired through our being-in-the-world, derived through the act of participation. As such, these concepts are not

fixed. They travel—between and across disciplines and the particulars of participants, contexts, and places. Varied sense-making paths emerge and as Bal explains they offer “... territory to be traveled in a spirit of adventure” (p. 23). It is the agency of these traveling concepts that Bal embraces for interdisciplinary work in the humanities. And, in seeking the lived terms of embodying the physicality and materiality of curricular multiplicities, I find similar traveling concepts to emerge, positioning all involved in attending to individual/collective co-curricular enactment from within the process itself—creating meaning—creating self (Macintyre Latta, 2013, pp. 14–21).

In what follows, these traveling concepts are identified and elucidated as curricular modes of being and doing. Grounded in Dewey's (1910, 1916, 1934, 1938) scholarship explicating knowledge and mind as verbs, giving flesh and blood to the ensuing “movement of thinking,” these traveling concepts are put in conversation with contemporary theorists, seeking a language for the associated participatory habits and interactive practices. Collectively, these theorists share a commitment to curricular conversations connecting self and world in an ever-enlarging conversation. Co-curricular enactment takes life, assuming continual adapting, changing, and building of individual/collective understandings. In doing so, the making of caring judgments en-route reveal again and again what it is to be human. The powers and possibilities of curriculum's multiplicities are illuminated through these participatory modes of interaction, revealing stories of humane becoming as integral within traversing such curricular terrain.

Meaning-making as elemental to being human

Dewey (1910) states that within the act of meaning-making “there is more than a desire to accumulate just information or heap up disconnected items In the feeling, however dim, that the facts which directly meet the senses are not the whole story, that there is more behind them and more to come from them, lies the germ of intellectual curiosity” (p. 32).

It is within physiological unease that Dewey (1910) claims curiosity manifests. Such unease may manifest as a question or wondering, through confronting an entirely foreign idea or perspective, or pursuing an unsettling feeling or stance that troubles what an individual knows. In doing so, curiosity's unease encounters ensuing multiplicities. Germinating sense-making terrain is incited. Such terrain assumes human beings interpret and make sense of their worlds through interactive engagement with these found multiplicities (Delaney and Mayer, 2021; Dewey, 1934; Dissanayake, 2015; Duckworth, 2006; Grumet, 1988; Johnson, 2007; Noddings, 1984). Such interactive engagement is personal—allowing for intersections with ideas, relations, and connections across multiple accounts; embodied—as it draws upon our lived bodily experiences that inform what we see, feel and respond to; and derived from narratives of experience—recalling prior narratives of experience and shaping narratives of experience ahead. Thus, individual/collective vulnerability is an ongoing accompaniment of germinating sense-making. Many contemporary education theorists articulate how entering into and living within such vulnerable terrain is necessary for genuine learning (Biesta, 2018). It is through the heightened visibility gained through individual/collective values, assumptions and beliefs made explicit, that prejudices are foregrounded, acknowledging the specifically situated and historically conditioned nature of all understandings. Gadamer (2000) explains “Whatever is being foregrounded must be foregrounded from something else, which in turn, must be foregrounded from it” (p. 305). Continually situating selves within such sense-making terrain gives life to the vitality integral to embracing the unfinished creative task of meaning-making as elemental to being human, fundamental to living itself. It is a vitality that incites curiosities that individuals may not know they ever had or could ever envision. Through embracing curricular enactment's multiplicities, interests germinate and foster ever-enlarging and deepening individual/collective understandings. “appealing to and fostering powers already active” within all participating (Dewey, 1910, p. 30).

Meaning-making as generative, mindful of place and process

Dewey (1916) states, “Never is method outside of material” (p. 65).

Dewey's insistence on the given particulars within every situation as the necessary starting place for all learning, puts mindful trust in the strengths, needs, and challenges of participants, context, and content, thus trust within unfolding contingencies. Collectively, these contingent multiplicities form what are particular and irreplaceable within each curricular situation (Chambers, 2008). Such investment is infused with emotional commitment in which learning is not simply an object or concept but permeated by a feeling or attitude that facilitates ongoing participation. Entering into relationship with learning in these ways insists on ongoing mindful attention (Aoki, 2005; Hansen, 2005; Ragoonaden, 2015; Rodgers, 2021; Van Manen, 2015). Dewey (1916) terms such mindfulness a confidence in process assuming a fitting organizing dynamic will emerge. The openings for seeing and responding within such an unfolding dynamic arise through building relations among students, teachers, context, and subject matter. It is these relationships that gather the materials informing curricular paths for intersections and deliberations. And, as these relationships emerge and develop between students and content, it is educators' and students' capacities to see, and concomitantly respond in ways that foster connections, through which curricular enactment comes into being. Derived through such an intimate understanding of situation, curriculum then is not applied or imposed as predetermined methods, techniques or strategies, but rather, unfolds as a mindful knowing in action that can never be fully anticipated. Learning can quickly become calcified without such intimacy.

Pinar (2009) conveys how conversing from within place, positions teachers and students to attend to the given and arising multiplicities as the generative materials of curricular conversations, building relations across self, others, and subject matter, offering productive ways to proceed. The generative movement of thinking that ensues is at the heart of what it means to educate. And, attention to this movement is the needed mindfulness for all involved. Thus, “mind” is understood as a verb assuming an inquiry stance

(Cochran-Smith and Lytle, 2009), seeking genuine concerted action from within process. The curricular task is to see what minds/bodies/spirits bring to every curricular situation. Aoki's (1992) pedagogical stance of tactfully following the pedagogic good in a caring situation provides guidance, making these multiplicities visible and then adapting, changing, and building meaning—moving minds/bodies/spirits. This stance is *watchful*—mindful of situation, relations, and action; and *thoughtful*—demanding a presence within the moment, taking in, receiving, and acting as situations call forth—oriented for learners'/learning's sake, deliberately seeking the well-being of students (p. 25).

Meaning-making as mindful curricular enactment is accessed through ongoing participatory contact and communication. Perceiving accordingly entails active searching alongside an intensely receptive responsiveness. Means and consequence or process and product simultaneously inform each other, rather than alternating or operating distinctively. Mindful curricular enactment generates a continual organizing and reorganizing experience, guided by the anticipation of the whole. For some time now, given concerns with compliance, uniformity, and standardization, teaching has been severed from notions of curriculum (Pinar, 2009). In such circumstances, setting pedagogical tone meant preparing students in advance to learn the curricular content. Such learning referred to covering/acquiring content and/or transferring knowledge. But, as pedagogy's roots suggest, to guide learners is to attend to pedagogical tone and conditions on a continual basis. Learning then entails creating the needed interactive context alongside continually seeking and building relations and connections across and among students, teachers, and subject matter. But, it is fear of the visibility and tangibility of relational multiplicities through curricular enactment that results in curricular enactment that separates form from matter, subject from object, and means from ends, and deliberately "obstructs", "deflects", and "prevents" (Dewey, 1934, p. 132) the needed vital interactions of Pinar's (2009) complicated conversations.

Meaning-making as in need of other(s)

Dewey (1934) states, "When the linkage of the self with its world is broken, then also the various ways in which the self-interacts with the world cease to have a unitary connection with one another" (p. 247).

It is lack of curricular room for multiple learning linkages with other(s) that devalues the roles of sense, feeling, desire, purpose, knowing, and volition within its enactment, instilling resistance, disregard, distrust, and fear as ways to exist according to Dewey (1934). Valuing these holistic participatory roles within sense-making of all kinds assumes that to learn about, with, and through other(s) is to create meaning, and concomitantly be created, always turning back on self through reciprocal interactions and modifications. Such reciprocal interactions and modifications, caringly connecting self and world, form curricular matter that very much matters. Thus, self-expression needs other(s). Dewey (1934) insists that it is the activity of the meaning-maker, each unique human being having a particular relationship to others, objects, events, and contexts, that converts an activity into an act of expression, holding "... together the various factors and phases of the self" (p. 252). Therefore, all understanding entails greater self-understandings.

Dewey (1934) maps out the reflexive interchange that exposes the makings of such expression beginning with impulsion, acknowledging the interdependency of self and surroundings, valuing resistance and obstacles, and enacted at the junctures of old and new encounters (pp. 58–60). Room to incite personal needs and interests manifests as participants are emotionally invested and guided by purpose and values. Embracing and following the creative flux, impulsion holds an agency all its own. Such agency values the active relations and intersections participants bring to situation. And, it is through the particular and varied narratives of experience that individuals confront and engage their understandings of self-in-the-world. Personal values, assumptions, and beliefs gain greater visibility to self and others. Seeing, hearing, and feeling one's way into thinking instills a belongingness that is interdependent with situation. It is belongingness that morphs through cognizance of selves within meaning making. And, such meaning-making reveals the importance of resistance and obstacles encountered to be productive. Feeling and interest, fear and hope, disappointment and elation must be concretely negotiated within meaning-making to value it as a self-confronting and self-challenging venture (Dewey, 1934, pp. 59–60). Living/learning accordingly takes life through the conjuncture of old and new understandings, through enlarging, deepening, and transforming sense-making through different situations and perspectives. Many contemporary learning theorists explicate how this reflexive interchange is not a solo venture but rather a venture that understands the centrality of the other(s) as being constitutive of the self (e.g., Bereiter and Scardamalia, 2016; Biesta and Stengel, 2016; Phelan, 2015; Pinar, 2019; Strong-Wilson, 2021; Rocha, 2020). They articulate how a separate sense of self is detached from the circumstances in which learning develops. They emphasize how a connected self is invested in the remaking of self. It is through the multiplicity of individual/collective connections that a movement of thinking is constructed and reconstructed in which all change in process with, from, and through other(s).

Meaning-making as temporal/spatial negotiation

Dewey (1934) states, "Space ... becomes something more than a void ... it becomes a comprehensive and enclosed scene within which are ordered the multiplicity of doings and undergoings in which man [sic] engages. Time ceases to be either the endless and uniform flow or the succession of instantaneous points ... it is an ordering of growth and maturations" (p. 23).

The multiplicities at play within attention to curricular agency and potentiality are more apt to be lost or undermined when learning space focuses on physical setting, excluding individuals' perceptions, emotions, and memories as present and infusing all spaces. And, further undermined, when time is understood as a commodity that controls and accounts for curricular planning and learning. Rather, Dewey (1934) "space-time" assumes a temporal movement of past-present-future within all sense-making.

Dewey terms this “a moving force” (p. 38). Attending to this movement of thinking from within the movement itself is depicted as “an ever-present process” (Dewey, 1938, p. 50). Delving into the nature of the present that positions teachers and students to seek the agency of “space-time” foregrounds what the immediate present gathers, what ought to shape the interactions taking place, and why it matters. Approaching curricular situations with this stance, understands that there is much already at play. Accessing these multiplicities, surfaces past understandings with implications for the future, while the immediate concerns and interests of the present ask all involved to seek worthwhile meanings for all involved. Time becomes a fluid organizational rhythm to be located within the present. Responsiveness to needs and challenges allows for multiple paces with varied pauses and rests, alongside a heightened sense of learning satisfaction and pleasure.

Active structuring of what is encountered on a continual basis becomes the curricular ground of “space-time.” Facilitating this ongoing structuring of meaning-making surfaces the role of growth within curricular situations as necessarily interdependent with “space-time.” Locating the needed sustenance for learners/learning within the present invests in growing individual/collective sense-making. It is such a turn towards the *contexts* for learning rather than the *causes* of learning that many contemporary theorists reiterate (e.g., Ayers et al., 2010; Biesta, 2007; Green and Reid, 2008; Hargreaves and Shirley, 2009; Palmer, 1998; Phelan et al., 2020; Wozniak and Fischer, 1993). In doing so, cautions are raised by discounting “space-time” including disconnected and numb learners and learning situations that history and contemporary times repeatedly reveal as being violent to individuals and violent to the world in-the-making (e.g., Battiste, 2013; Freire, 1970; Jardine et al., 2006; Kincheloe, 2008). It is the acceptance and surrender to “space-time” that must be heeded through understanding the lived costs of predetermined curricular control closing off opportunities afforded through attention to given multiplicities. Rather, embracing control as direction for learning derived or found through attending to the multiplicities shaping learning as a “moving force,” holds the potential the world keeps avoiding and fearing.

Meaning-making as imaginative, instilling embodied understandings

Dewey (1934) states, “Roominess, a chance to be, live, and move” (p. 209).

Dewey’s (1934) notion of roominess assumes participants are in-touch with context, seeking fitting ways to respond accordingly. The body’s role within sensemaking assumes that the human body is not separate from the mind, nor thinking from feeling, nor individual from social. Rather, such dualistic thinking is nonexistent within the needed reciprocal relationships of what Dewey (1934) terms, “mind-body” (p. 227). Curricular roominess allows for such reciprocal movement, actively making room for a multiplicity of suggestions accessed through mind-body multi-sensory mediums of deliberation, intuition, anticipation, natality, and enlarged realizations (Macintyre Latta, 2013, pp. 66–72). These mediums rely on embodied opportunities to make meanings that are interdependent with imagination as a means to image-forth possibilities. Deliberation images forth greater flexibility, learning through unexpected ways of being and responding. Intuition images forth greater trust within sensemaking processes. Anticipation images forth learning connections again and again, recursively enlarging individual/collective prior understandings. Natality images forth a plurality of tensions and differences as catalytic within all sensemaking. Enlarged realizations image forth continual learning momentum with conclusions understood as momentary syntheses that push forward into new learning terrain.

Thus, imagination serves as imaging-forth gateways into illuminating and appreciating multiple understandings (Baldachino, 2009; Greene, 2000). And, these understandings are further instilled through embodied mediums for seeking roominess within curricular enactment. But, it is the communicative, relational, and interactive multiplicities revealed through roominess within curricular enactment that many contemporary theorists document as being undermined and thwarted (e.g., Donald, 2009; Eisner, 2002; Irwin and de Cosson, 2004; Kumar, 2013; O’Loughlin, 2006; Sidorkin, 2002). Communication’s expressive powers can be hidden and suppressed through top-down curricular mandates and prescriptions repressing and controlling participation. Relational connections to subject matter are avoided when knowledge is understood as separate and disembodied, excluding interest, care, and pride in self and learning. Interactive practices are foreign if never or rarely engaged. The significances for learners and learning lacking lived embodiment of communicative, relational, and interactive multiplicities are lost through regulated curricular enactment divorced from the multiplicity of relational complexities intersecting through time, space, context, and participants.

Imaginary roominess for deliberation, intuition, anticipation, and natality open into multiple curricular paths and forms of engagement that compel participants’ “surrender and reflection” within the sense-making process itself (Dewey, 1934, p. 53). Such surrendering and reflecting opportunities are experienced as embodied impacts that hold the significances to be discovered through expressive communications, self-understandings, and found purpose occupied with forming learner/learning connections (O’Loughlin, 2006; Varela, 1997). It is the human body—living, being, moving—that needs to be entrusted with sense-making and empowered through curricular roominess, way-finding.

Meaning-making as reflexively informing self-understandings in relation to wider contexts

Dewey states, (1943), “the great thing for one as for the other is ... education which enables him [sic] to see within his [sic] daily work all there is in it of large and human significance” (p. 24).

Multiple reflexive opportunities to renew understandings of self through varied perspectives, invite concrete connections with others and embrace the agency of knowledge-building discourses. It is this agency that Dewey (1916) explains reframes individuality away from self-sufficiency and independence toward revising and transforming personal values, assumptions and beliefs, interdependent with openness to other(s) (p. 295). The needed attitude or stance taken must be one of ongoing inquiry rather than

mastery. The recursive opportunities availed for such self-renewal foster a dynamic rhythmic movement of thinking, positioning participants to locate selves within the given contexts, thus continually adapting, changing, building understandings of self in relation to the world. Contemporary theorists confront the need to recover a broader sense of world in which participants can break free from the “cage of subjectivity” (Smith, 2006, p. 80) confining self-understandings (e.g., Hansen, 2011; Kerdeman, 2003; Nussbaum, 2010; Pinar, 2011; Stitzlein, 2020; Waks, 2009). It is the opportunities seized to situate self within what is known and what is not known, said and unsaid, visible and invisible, that makes more explicit multiplicity’s renewing capacities and their lived consequences.

Knowledge-making discourses share a primary concern for attention to learner-learning connectedness mediated through the multiplicity of relationality. Seeking such connectedness invests in the particulars of self and situation first. Therefore, connectedness attends to histories of individuals and situations, positioning participants to confront these givens. Genuine concerted action is prompted as participants scrutinize connections and an individual/collective reorganizing movement of thinking manifests through divergent learning processes and products, divergent perspectives, traditions, and experiences. It is integral that participants respect and value such differences as catalysts for sense-making, placing more and more confidence in the reorganizing movement concerned with emergence and ongoing development. Spending more time and concrete practice living in such connected ways in classrooms is a pressing concern of many theorists. It is such concrete curricular enactment that they envision as enabling participants to live better in the world with others, seeking humanity’s common wealth and the needed modes of being to reside well together (Gaudelli and Hewitt, 2010; Granger, 2006; Hansen, 2011; Noddings, 2013; O’Loughlin, 2006; Pinar, 2009; Stitzlein, 2020).

The primacy of being faithful to all that unfolds through given multiplicities as shaping the task of curricular enactment, positions educators alongside their students residing at the nexus of curricular situations and interactions. Residing as such fosters heightened awareness of the choices that educators make and their consequences for learners/learning attending to the conditions and ongoing creation of genuine learning contexts. Such awareness demands that educators see what is at stake in given situations and further the movement of thought in self and others. Educators and students embrace the agency as integral to human flourishing (Cherkowski and Walker, 2018). Thus, curricular enactment embracing multiplicities is never scripted, nor formulaic, but rather, take multiple forms, interdependent with the particulars of situation. Such curricular enactment importantly emphasizes the catalytic role of educators committed to this pedagogical stance, alongside emphasizing the impacts for learners and learning, invested in growing strong student identities valuing interactions, deliberations, and debates. It is the difficulties, distances, and ideas comprising diverse multiplicities of interactions, deliberations, and debates that hold the significances for learning and learners. Curricular enactment so conceived is living inquiry, attentive to the givens of context, the particulars involved, and the relational complexities that ensue, generating seeing and acting to further learners/learning.

Curriculum's multiplicities as prompting humane becoming

Curricular multiplicities are brought to life through meaning-making’s elemental connectedness to being human, meaning-making’s embracing of the given within all situations, meaning-making’s need of others, meaning-making’s spatial/temporal agency, and meaning-making’s interdependence with imagination, instilling embodied understandings. Collectively, these interdependent and participatory modes of being and doing initiate the much-needed curricular terrain for educators alongside their students to see and act within the fecundity that transpires, bringing “... curriculum to life—to recapture the creative energy of all life, the esthetics that exist in being ...” (Doll, 2002, p. 34). The fecundity is characterized by Doll (2013) as “rich”, “related”, “recursive” and “rigorous” (pp. 215–222). And, it is the multiplicities traversed through the rich, related, recursive, and rigorous curricular terrain that bring all participants near to the moving particulars of situation and interaction. Such a lively spirit, seeking ways to proceed for learners/learning by attending to the sense-making terrain, holds tremendous potential to reframe education away from competition—good and bad students, teachers, schools, and communities; away from imposed top down controls—monolithic policies, methods, and practices; and, instead, invest within genuine learning experiences that foster strong student identities, growing strong school cultures, facilitated by strong educators and communities laboring to understand themselves and the work they inhabit. Enhanced educator and student empathy, openness, appreciation of differences of all kinds, and valuing of the process character of interactions, translate into greater self-understandings and learning confidence alongside developing capacities to live better in the world with others (e.g., Apple, 2013; Biesta, 2013; Groundwater-Smith and Mockler, 2009; Jardine, 2012; Macintyre Latta, 2018; Noddings, 2012; Stengel, 1991).

Troubling this account of rich, related, recursive, and rigorous curricular terrain is Doll’s (2002) attention to what he terms the curricular “ghost of control,” as a persistent haunting encounter that continues to thwart and betray the needed “livelier spirit of control” within curricular enactment across disciplines and interests of all kinds. This is not new thinking, but it is bold thinking that world-wide curricular enactment in schools and communities persists in avoiding and short-changing. The participatory modes identified through curricular enactment’s multiplicities reframe understandings of education and knowledge invested in such a livelier spirit of control. What education and communities need to embrace is just how lively, how revolutionary, the ensuing meaning-making modes can be, holding, the powers and possibilities of curricular enactment that is oriented toward learner/learning growth, greater self-understanding, enhanced well-being, and the opportunity to continually situate self in the world alongside others. Such meaning-making can be a vital medium for embodying and strengthening the roles of education within all institutions and communities, locally and globally (Tierney, 2018). It is world-wide human preoccupation with what Doll (2002) describes as “a method to bring control and order to life” that he argues haunts curricular visions (p. 34). Taking up Doll’s challenge to “ferry this spirit to the

other side," (p. 28) points to the primacy of investing in curricular enactment's multiplicities as disrupting long-held colonial learner/learning relationships (e.g., Archibald, 2008; Donald, 2012; Hare, 2016; Lowan-Trudeau, 2014; Ragoonaden and Mueller, 2017). The complex relational ground comprising the participatory modes of being and doing constitutes what Leggo (2007) conveys as "... a way of communing with others, with the whole of Creation; " a stance that sees the relational whole, "... calling out ... to other human beings on hopeful journeys of humane becoming" (p. 165). The phrase, hopeful journeys of humane becoming, sums up the impacts of curricular enactment's multiplicities in action. Not only does the phrase offer a wonderful way to respond to fundamental curricular questions concerning the nature of education and knowledge, but also, in emphasizing hope, it assumes potential in self, others, and situation; in drawing upon the notion of journey, it assumes movement; in grounding the venture in the uniqueness of individuals, it foregrounds humaneness; and in operationalizing the phrase through becoming, it assumes an ongoing mind/body/spirit/wholistic process, inviting participants to be and to become, again and again.

Collectively, curricular multiplicities offer ways to be and become through curricular journeys revealing how given situations and particulars shape the individual/collective movement of thinking incited and explicate how these journeys unfold as fundamentally contextual. Openness to the unanticipated is key alongside acknowledging that something is always already at play. Responsivity is assumed, inciting movement very much animated by the spirit of all that forms/informs each journey. It is after all the relational workings of self and other(s) encountered on each journey that explicates these features, suggesting a way to proceed and, concomitantly, bringing selves into being too. The connectedness to co-curricular-making manifests across disciplines and interests of all kinds, fostering the curricular conditions for ourselves and our students to continually locate and relocate themselves on varied curricular paths, creating meaning, creating self—heeding the call to journey with others in life's ventures, embracing learning as life-giving. The ongoing search, locating selves within these curricular journeys, is what it is to be alive. Furthermore, the research literature over the last two decades reveals that the world is only recently awakening to how such meaning-making finds kinships with long-held beliefs and modes of being embodied within Indigenous wisdom traditions (Arrows et al., 2010; McKinley and Tuhiwai Smith, 2019). World-wide, Indigenous connections to land, culture and the relational self, convey the need for such kinships (Haig-Brown, 2010; Kanu, 2011; Ng-A-Fook, 2014; Styres, 2017). And, it is within seeking such connections that the kinship of Indigenous commitments to interconnectedness, reciprocity, relationality, reverence and respect, emerge and offer the needed learning conditions, supports and participation toward decolonizing curricular efforts (Atleo, 2009, 2011; Archibald, 2008; Battiste and Henderson, 2009; Cajete, 2015; Dion, 2009; Donald, 2019; Carter et al., 2015; Cohen, 2001; Arrows et al., 2010; Restoule et al., 2013).

Current times offer no shortage of how multiplicities hold many teachings. The local/global intersections are blatantly apparent. For example, arising through escalating strife, given Russia's invasion of the Ukraine; the realities, intersections, and impacts of Truth and Reconciliation efforts; Black Lives Matter movement; and Orange Shirt Day confronting the violence of Residential Schools. This cross section of current concerns open the door to world-wide conversations on race, racialization, and racism, and reveal the genocidal legacies of ongoing costs and long-term learner/learning consequences; and the coming together of Indigenous, Black, and People of Color re concerns for equity, justice, and associated societal changes; with all foregrounding how systemic racism and monolithic thinking excludes and marginalizes, and have been and are, extremely harmful. In support of all human beings, movements such as SOGI 1 2 3 foreground how schools must be inclusive and safe for students of all sexual orientations and gender identities (SOGI), emphasizing the importance of gender and sexual orientation not limiting interests and opportunities, and where time and space to understand and express gender and sexualities are welcomed without discrimination. As the COVID-19 pandemic (2020) persists with unprecedented global impacts on societies, highlighting the disparities among individuals and nations, it importantly implicates how human connection, well-being, and health are intricately tied. Climate change, biodiversity, and the dire consequences of ecological imbalance are now much more commonly understood as shared urgent world concerns. This cross-section of global multiplicities is heightening worldly attention to human beings/non-humans/Mother Earth connectedness, foregrounding education's roles and responsibilities. Curricular multiplicities as participatory modes of interaction position all of us as complicit within situations together, world-wide. Such complicity entails investment within long-term human/non-human well-being in a shared world, productively reframing education locally, nationally, and internationally. Curricular enactment embracing its multiplicities, forms the much-needed practice ground that can no longer be ignored. It reframes education away from competition and imposed control and toward individual/collective growth and well-being, exposing the fertile ground of sense-makings' multiplicities and offering the sustenance the world needs to think and act together; collectively taking seriously ways to live well in the world with all our relations. Curricular multiplicities as participatory modes of interaction position all of us as complicit within situations together, world-wide (Noddings, 2012).

The conjunction of education and identity is a familiar trope; it is the core of the bildungsroman that characterize English curricula of the global North: education forms one's identity on the page and through the page. The curricula of this education can be formal and informal and are often connected to identities of survival and belonging. We are reminded, for instance, of Lucy Maude Montgomery's classic Canadian Anne novels (e.g., 1908), where protagonist Anne Shirley clutched to poetry to sustain her through the trauma of being an orphan, her adolescence in an adoptive family, and the pursuit of academic success, all to prove herself worthy of calling Green Gables home. More recently, there is Elena Ferrante's Neapolitan quartet (2012, 2013, 2014, 2015), an ocean and decades away from Anne's rural Prince Edward Island but similar in its treatment of education and identity. Set in the violence of a poor Neapolitan neighborhood in the 1960s, Ferrante's Elena Greco is schooled through the curriculum of that neighborhood, as well as the curricula of a hard-won institutional education, and at the hand of her brilliant, unschooled friend, Lila, all with effects on and implications for her identity.

There is, of course, more to say about these novels, but our point is not the novels themselves; instead, we begin an article about curriculum and identity options with a reminder of the bildungsroman to indicate the ubiquity of the concurrence between the concepts and to use it to argue that it is this very ubiquity that creates a danger of taken-for-grantedness about the potential link between curriculum and how and what identities may be. Tracing conceptualizations of identity becomes central to thinking with identities and what it might mean to have *identity options*. As such, we offer in this article opportunities for readers to see identity in/out of curriculum studies as a concept that has been diversely treated with each treatment having its own implications for curricular research and practice. We begin by offering a primer on conceptualizing curriculum and identity options. We then move through a history of curriculum and the ways in which each movement in the field has brought various ontological, ethical, and epistemological resources to the conversation of identity. We present a version of history that is tripartite in its construction: the emergence of the field to reconceptualism(s), including the rise of socio-cultural and poststructural theories, and into posthumanities. The construction is perhaps overly teleological yet provides a trajectory of theorizing that may be helpful to apprehending some resources of import for thinking with identities and curriculum.

Curriculum and identity options

Curriculum is a concept that has been diversely conceptualized. To deal with the multifaceted nature of curriculum conceptualizing, we call for qualifying what one means by curriculum, as we do in this article. Thus, we might speak of identity and *institutional curriculum*, (i.e., shared and abstract goals for education that respond to schools' socio-cultural and political contexts and demands (Doyle, 1992)), *programmatic curriculum* (i.e., written curriculum documents and materials for use in teaching (Doyle, 1992)), *classroom curriculum* (i.e., what actually happens in the classroom (Doyle, 1992)), *hidden curriculum* (i.e., values and messages that are implicitly learned through curriculum, but that are not explicitly taught (Apple, 2004)), *null curriculum* (i.e., that which is absent from being explicitly and implicitly taught, with its absence having implications for students' learning, knowledge, and values (Eisner, 1979)), *lived curriculum* (i.e., the phenomenological experience of a curriculum (Aoki, 1993)), and so on, marking specifically the concept and its origin(s) in the literature through our citational practices.

Much like curriculum, there is no single response in the literature to what identity is, what it does, or how it works. However, many theorists in diverse areas of scholarship have scrutinized the term. Gleason (1983) explained that its use is relatively recent in the social sciences. According to him, in the 1930s, when the first edition of the *Encyclopedia of Social Sciences* (Seligman and Johnson, 1930) was published, the term identity was not included in it, and, by 1968, only two entries contained the term. One conceptualized it by connecting it to psychosocial phenomenon (Erikson, 1968) and another to political affiliation (Buchanan, 1968). In 1983 when Gleason published the treatment of identity to date, he noted that though many areas of research had attempted to explain what identities are and how they are produced and expressed, there was no consensus on its definition or

conceptualization; a situation that our literature review in this article finds is still the case. There are numerous conceptions and uses of the term identity; conceptions that Gleason's research indicated were focused either on the individual and internal, psychological processes or more external, social processes of identity formation. He noted that Erikson (1963), for example, advanced a psychological approach to identity, connecting it to something internal and developmental, spanning across the lifecourse. An oppositional definition supported by sociologists is that identity is fluid, constantly changing according to context and social experiences (Gleason, 1983). As we will discuss below, identity was not on the radar in education when curriculum studies emerged; however, scholars in the field were concerned with the kinds of citizens institutional and programmatic curricula were trying to craft. The second movement of the field afforded the phenomenological conceptualization of *lived curriculum*, bringing identity to the fore. Shortly thereafter, socio-cultural theorizing birthed the notion of identity options.

Identity options refers to the ways in which all forms of curricula affect how learners can see themselves and their place in the world. This concept was extensively explored by Cummins (2000) in his work with culturally and linguistically diverse learners. Cummins (2000, 2001) argued that interactions between educators and learners are permeated with power relations with the potential to expand or constrain learners' academic engagement and affect their sense of self as competent learners. Cummins (2009) conceptualized power relations in learning spaces as collaborative or coercive. *Coercive relations* indicate control, hindering identity options for students; *collaborative relations* allow for power to be distributed among educators and learners, enabling recognition of learners' identities as valuable resources for curriculum making. One form of expanding learners' identity options is through *identity texts* (e.g., Cummins, 2006). Identity texts are said to promote equitable pedagogies that affirm diversity and learners' competence, expanding their identity options by allowing multiple modes of communication (e.g., visual, gestural), and welcoming diverse cultural knowledges and languages in students' academic productions. Cummins and Early (2011) explored the potential of identity texts in framing language learners in a positive light in multilingual educational settings. Their studies illustrate how learners benefit from pedagogies that enable them to express themselves in their own terms and through a multitude of resources.

Other researchers have also taken up the concept of identity options in investigations of multimodal literacy practices in intergenerational programs (Heydon, 2007), early literacy curriculum (Heydon et al., 2015), and transnational education (Zhang et al., 2020). Heydon and O'Neill's (2016) introduction of singing as a multimodal literacy practice into an intergenerational art program, for example, demonstrates that "expansive literacy options correlate with expansive identity options" (p. 136). The singing and art infused curriculum allowed elders and children to move across modes, experimenting with meaning-making practices that they might not have experienced without their peers' encouragement or in a narrower programmatic curriculum. The authors highlighted how "the bodily and vocal gestures that accompany singing articulate meanings and emotional states that when combined constitute a particular narrative" (p. 133). These narratives generated new forms of expression that allowed participants to define and share "aspects of who they are, who they were in the past, and who they might be in the future" (p. 133). Heydon and O'Neill's research illustrates how multimodal intergenerational curricula can offer opportunities for identity negotiation and expansion through relationship building and semiotic experimentation. Pedagogies that prioritize identity options aim at empowering students by creating a sense of belonging and expanding opportunities for them to express and pursue identities through myriad resources within and beyond canonical knowledge.

To understand how the concept of identity options sits within curriculum studies, its epistemological and ontological roots, commitments, and where its constraints might reside, we now turn to a discussion of identity and curriculum in the literature, moving from the early days of the curriculum studies field to contemporary theorizing.

Emergence of curriculum studies: identities on the horizon

The early history of curriculum as a field of study did not explicitly name identity. Identity was surely, however, part of the hidden curriculum. Much of the early field concentrated on the development of educational systems that would promote students' efficient and effective acquisition of skills and knowledge. Consider, for example, the twinned foci of scientific knowledge and economic growth from the United States which drove the shape of curriculum studies in the 1900s (Ingersoll et al., 2019). Bobbitt (1916, 1918) and Tyler (1949) are remarkable names of an era in which curriculum scholarship followed a course of "control, measurement" (Null, 2008, p. 479) and outcomes that were at the heart of many academic fields, though Dewey (1902) offered an early hint of the attention to identity and lived curriculum that was to come.

In the beginning of the 20th century, modern science advanced quickly, and education followed by adopting a discourse and logic that were compatible with the happenings of that context. Questions of curriculum were mainly those of programmatic curriculum and were answered "in the language of science" (Null, 2008, p. 479), with key concepts being objectivism and efficiency in relation to curriculum *development* and *transmission* (Doyle, 1992). Bobbitt (1918) envisioned that curriculum should be directed toward creating the kind of adults that could take their place within an industrial society (Null, 2008). His major work, *What the Schools Teach and Might Teach* (1916), outlines how observing adult life activities could help determine programmatic curriculum components that would build such citizens. In this orientation to curriculum, a technology of curriculum development and application could produce direct, predictable effects on people, including creating desired citizens (Null, 2008).

Also working in the vein of curricular efficiencies directed toward prescribed ends, is the oft-cited (e.g., Finder, 2004; Wraga, 2017) and analyzed (e.g., Kliebard, 1970, 1995) Tylerian rationale (Tyler, 1949). Tyler granted that a scientific process of teachers and school administrators responding objectively to a prescribed set of questions would, within his rationale, result in the

identification of “an effective educational program” (p. 125). The rationale was predicated on the idea that curricular experiences, once organized and planned, could generate the behavioral outcomes curriculum makers intended (Deng and Luke, 2008). With both Bobbit’s (1916, 1918) and Tyler’s (1949) models for curriculum development, we see curriculum conceptualized as something that could, with the right design, move smoothly from what was intended to what would be enacted. Curriculum was *done to* learners with the production of prescribed citizens or workers part of the hidden curriculum.

Contemporary to Tyler and Bobbit was, of course, Dewey. Although Dewey did not explicitly speak of identity, his focus on learners and their knowledge and experience opened the door for its later conceptualizations to come. Works such as *The Child and the Curriculum* (1902), were anathema to efficiency models of curriculum that separated knowledge from experience and the child from society. His work also renders problematic any idea of programmatic curriculum being directly translated into classroom curriculum; for instance, in talking of the “course of study”, Dewey expressed, “no such thing as imposition of truth from without ... All depends upon the activity which the mind itself undergoes in responding to what is presented from without” (p. 31). In statements like this, Dewey foreshadows what Schwab (1973) would later name the curricular *commonplaces* of educator and learner and shows some of the complexity of curriculum-making.

Dewey did not explicitly deal with identity as we would recognize the concept today; nonetheless, work like *The Child and the Curriculum* (1902) drew attention to learners and their experiences, demanding that learners be at the center of curriculum, ideas that were important for later identity theorizing in education. Of his foci, Null (2003) indicated that Dewey “admonished teachers not only to focus on subject-matter, but also to concern themselves with the needs, interests, experiences, and backgrounds of their students” (p. 66). Bringing learners into view in curriculum-making was expressed by Dewey and other *pragmatic progressives* as an important aspect of curriculum inquiry, alongside a focus on problem-solving and democratic participation (Wraga, 2019). According to Reese (2001), American progressivism also included child-centered ideas that challenged traditional schooling and rearing practices reflecting some of the shifts occurring in that period, such as changes in “family size ... gender roles ... and the softening of religious orthodoxy within Protestantism” (p. 3). Scholars such as Ingersoll et al. (2019), articulated one of the major differences between efficiency curricular models (e.g., Tylerian rationale) and Deweyan progressivism as a movement from viewing students as passive receptors of skills to understanding the child’s “experience of schooling” (p. 2).

Modernism and scientism placed emphasis on linearity, predictability, and reproducibility to understand human behavior and development. A critical understanding of identity had no place in this form of curriculum theorizing. Social movements and curriculum reconceptualization were about to change this.

Curriculum reconceptualization and an emphasis on identity

The reconceptualizing of curriculum was a turn toward the learner, their social positioning and relationship with/in curriculum writ large. It was a catalyst for explicit considerations of identity and a challenge to objectivism and dominant positivist paradigms of curriculum development (e.g., Pinar, 2008). The movement ignited multidisciplinary scholarship that considered curriculum in its interrelation with social concepts and identity markers like race, gender, and culture (Pinar, 2004). Robson and Sumara (2019) explained, for instance, that “the idea that our identities are at least in part the product of our socio-cultural environment grew from several streams of thought” (p. 146), and they pointed to grassroots movements led by feminist, black and LGBTQ+ activists in the 1970s, who pushed the boundaries of objectivism and universal truths by creating spaces in which previously minoritized experiences were debated and acknowledged.

Around the world, civil rights movements gained force while critical and then post-structural theories spread in/through curriculum studies and beyond. These new epistemic resources fueled a (re)consideration of seeing and doing education. Critical theory, for example, scrutinized how schooling and curriculum reproduced social inequalities, interrogating whose knowledges and interests were served by them. One of the most prominent names of critical pedagogy is Paulo Freire (1970), who advanced the idea that education should emancipate individuals instead of operating from a banking model in which the knowledge that education deposits into the learner is what one may withdraw—independent of who the learner is or their socio-cultural situation. Freire put into practice many of the tenets of critical theory in developing literacy projects where all curricula were based in learners’ own cultural and linguistic contexts. Literacy curriculum, in this way, was directed toward affirming learners’ experiences and identities while creating educative opportunities that raised their consciousness of how socio-political issues affected their lives. The question-to-come of identity options was also opened here with the focus on curriculum as related to power.

Integral to this movement was the questioning of curriculum and cultural and racial identities (Jackson, 1992). Robson and Sumara (2019), for instance, asserted that schools were spaces of competing values, where *hidden curriculum* operated through biases in the system, communicating that some knowledge was more desirable and desired by the cultural elites than others. Castenell and Pinar (1993) dug deeply into investigating *curriculum as racial text* as they sought to theorize representation, identity, and difference in education. In this work, they conceptualized identity as “a gendered, racialized, and historical construct” (p. 4), highlighting its situated socio-political nature. They also made the link between identities and curriculum explicit by considering curriculum a “significant form of representation” (p. 2), stating that “identity formation is constructed and expressed through representation, that is, the construction of ‘difference’, and negotiated in the public sphere” (p. 4). Further, Pinar (2008) expounded that multicultural education grew from an effort to acknowledge cultural diversity; however, he cited McCarthy’s (1993) critique alerting to the dangers of acritical notions of multiculturalism and exposing the complexities of race. He invited curriculum theorists and educators to recognize race and how it was part of curricula, textbooks, and pedagogies. He reprized his call with Castenell and Pinar (1993)

demanding that scholars engage with the complexities of race, rather than trying to find single solutions to racism or neglect how race was instantiated in curriculum and permeated experiences of learners and teachers.

Feminist theorizing and identities

The reconceptualization of curriculum was equally forwarded by critical feminist scholarship that laid the groundwork for future conversations of identity. This scholarship challenged education's sense of normalcy and (re)production of constraining gender and sexual roles. A key example is [Luke and Gore's \(1992\)](#) *Feminisms and Critical Pedagogy*, a collection that questioned progressive education and critical pedagogy for their lack of attention to the diverse ways language, power and knowledge operate depending upon one's social positioning and subjectivities. Bringing to the fore foundational feminist pedagogues of the era, each article confronted traditional understandings of critical pedagogy by exploring the localized experiences of women in academia. Challenging the generalizability of theoretical developments and pedagogies of masculine authorship, including a masculinist notion of emancipatory critical theory, the collection focused on the complexities and multiplicities of subjectivities, exposing how dominant educational and political discourses impact women's, children's, and racialized bodies. Their poststructural feminist analysis entwined research practices, theoretical thinking, and personal accounts, bringing identity to the forefront.

Collectively organizing, feminists of the day fashioned spaces for women to speak and be heard. The concepts of *voice* and its absence appear frequently in scholarship of the movement; for instance, [Lewis's \(1993\)](#) *Without a Word: Teaching Beyond Women's Silence* drew from her teaching and academic experiences to reveal "the lived contradiction between silence as oppression and silence as revolt" (p. 2). Lewis acknowledged that women's speech is transgressive and political. As such, her writings can also be understood as acts of defiance to dominant male voices in education. [hooks' \(1989\)](#) toiled with the idea of *voice* to fill up voids in educational theory in relation to racialized women's identities. Her collection of essays, *Talking Back: Thinking Feminist, Thinking Black*, tackled racism, feminism, pedagogy, and politics through an embodied perspective where her experiences as a black woman generated theory. [Kelly \(1997\)](#) introduced questions of affect and desire into conversations of identity in *Schooling Desire: Literacy, Cultural Politics, and Pedagogy*. Leaning on her schooling experiences in rural Canada, Kelly rethought the ways in which traditionally organized literacy curricula produce identities and regulate desire. She advocated for a consideration of how pleasure might enter curricula to challenge educational inequities, and her work encouraged the inclusion of feminist orientations to curriculum theorizing, arguing that they could open avenues for considering how "knowledge, power, and desire" (p. 1) operate through curriculum and affect identities.

The branches of the reconceptualist movement in curriculum, each in its own way, brought about new modes of thinking about education, questioning its purposes, who was responsible for making curricular choices, and the implications or effects of these choices ([Eisner, 1992](#)); a contiguous branch of this movement pursued a critique of traditional curriculum theory through phenomenology, and created additional resources for conceptualizing identity. Foremost among these is Ted [Aoki's \(1993\)](#) *lived curriculum*.

Phenomenological theorizing and identity

[Aoki \(1993\)](#) argued that the curriculum landscape of the day privileged *curriculum-as-plan*. Akin to the concept of the programmatic curriculum ([Doyle, 1992](#)), Aoki's curriculum-as-plan is a curriculum created by those who reside outside of the classroom (e.g., curriculum specialists, governments, etc.). This plan is what teachers (and students) must follow; it is not neutral because it is created by people and institutions and thus enmeshed with their philosophies/values of learning and knowledge. Prioritizing some knowledge and omitting the rest is sedimented in statements of intent, curricular goals, and objectives. Aoki critiqued the ways curriculum-as-plan divided knowledge into "epistemic categories" (p. 256), separating arts and sciences and creating a "curriculum topography" (p. 256) that represented Western Cartesian ways of organizing the world. Aoki attested that students' experiences often diverge from curriculum-as-plan. Whereas curriculum-as-plan is developed outside the classroom, using techno-scientific language to describe curriculum goals and intentions and "written for faceless people in a homogeneous realm" (p. 261), the lived curriculum is phenomenological, "embodied in the very stories and languages people speak and live" (p. 261).

[Aoki's \(1993\)](#) lived curriculum is "not the curriculum as laid out in a plan, but a plan more or less lived out" (p. 257). Lived curriculum refers to learners' and educators' curricular experiences or how they experience curricula. This curriculum, according to Aoki, is complex as there are likely as many lived curricula as learners' identities. Identities, for Aoki, are effects of curriculum in relation to learners, educators, in ongoing *becomings* these becomings are counter to a fixed, immutable conceptualization of identity. Identities and curriculum emerge in the *in betweenness* and tensions that exist in the curricular landscape of curriculum-as-plan and lived curriculum. This space produces possibilities for doing identities and curriculum in new ways.

According to [Aoki \(1993\)](#), to robustly comprehend curricula, one must recognize the tensions of curricular landscapes and how they create a multiplicity that "grows in the middle" (p. 259). Citing [Deleuze and Parnet \(1987\)](#); [Aoki \(1993\)](#) described that identities are not pre-existing but "ongoing effects of our becomings in difference" (p. 260). That is, identities emerge from relationships with others; they grow in the middle. Perhaps Aoki's separation of lived curricula and curriculum-as-plan reflects the very Cartesian separation that he rejects. However, this split of curricula promotes how lived curriculum and curriculum-as-plan are always enabling, producing, reproducing, or constraining these becomings. Aoki evoked postmodernist thinking, citing [Lyotard's \(1984\)](#) questioning of grand narratives of unity, rationality, and progress, and called for curriculum theory to do the same. Aoki suggested that curriculum should embrace the multiplicity of curriculum stories "legitimizing thoughtful everyday narratives" (p. 263) that unsettle curriculum, education structures, and the objectivity and separability (between categories of knowledge,

for example) in which they are founded. Furthermore, Aoki argued educators must move away from privileging curriculum-as-plan toward finding creative, open spaces in between curricular landscapes, that offer possibilities for learning to take different directions based on who learners and educators are and the contexts in which they live, giving “way to a more open landscape that offers possibilities by, in part, giving legitimacy to the wisdom held in lived stories of people who dwell within the landscape” (p. 267). Aoki called for knowledge and wisdom to be considered together through the recognition of educators’ competency as curriculum makers.

Lived curriculum was related to other crucial curricular theorizing of the movement that had implications for identity. In 1975, Pinar provided additional resources for shifting curriculum from techno-rationality by introducing the concept of *currere*. *Currere* is the Latin root of curriculum, meaning “the running (or lived experience) of the course” (Pinar, 2004, p. xiii). The idea of curriculum as a racecourse emphasized its continuous and dynamic trajectory, but enabled understanding curriculum theorizing, producing, and experiencing as a verb, focusing on the lived, embodied and negotiated experiences of learners. Pinar (2019) stated that curriculum is a “complicated conversation” (p. 50), in which “curriculum as plan” (p. 51) and curriculum as lived experience are often in relation to each other. Pinar explained that *currere* as a verb in its infinitive form, includes “actions, processes, and consequences” (p. 51), whereas perceiving curriculum as a noun eliminates its complexity, investing in the traditional idea of curriculum as a document that establishes what learners need to know to achieve pre-established goals. Corroborating Aoki (1993), Pinar (2019) said that “curriculum as plan” (p. 51) ignores the vibrant complexities of social, political, cultural aspects of life that are constantly in motion. For Pinar, this lived curriculum is embedded in a “subjective sphere” (p. 51) that is not present in institutional goals and efficiency orders. Rather, curriculum has consequences that can disturb any possible predictions of its outcomes (much as Dewey (1902) previously taught): “the consequences of academic study are ongoing, as they are, in lived terms, social and subjective as well as intellectual. Outcomes are, finally, immeasurable” (Pinar, 2019, p. 51). *Currere* also establishes a focus on identities in their relationship with all forms of curriculum. Pinar explained that *currere* concentrates on individual learning but recalls that learning always happens in relations with others since education and curriculum experiences are socially, politically, culturally, and economically situated. Pinar emphasized the power of curricular experiences and their impact on individuals by stating, “we are changed by what we study; such educational experience encourages subjective and social reconstruction” (p. 51).

An additional element of *currere* as it relates to conceptualizing identity is *difference*. Pinar (2019) extolled the value of difference calling for attention to the ways people become who they are. He stated that every person

has a different genetic and social makeup: different upbringings, families, and caretakers, and significant others like teachers. We are also different (and similar) in terms of race, class, culture, and gender, inflected as these are by place, time, and circumstance. While informed by these and by other homogenizing forces, each of us is, or can be, distinctive. Indeed, the method of *currere* invites us to cultivate that distinctiveness (p. 51).

Currere demands that learners and educators engage in ethical and reflexive practices that cultivate a “consciousness that remembers the past with an eye on the future while focused on the present” (p. 52). The method of *currere*, according to Pinar (2019) has four phases that would allow enacting “the concept of curriculum as self-formation through academic study and dialogical encounter” (p. 52): the “regressive phase” allows learners to return to the past and remember significant experiences; the “progressive moment” requires that learners imagine their future; the “analytic moment” calls learners to contemplate past and present experiences together and find what has been “obscured” or “neglected” in their lives, opening up new possibilities for subjectivities; and the “synthetic phase” allows the person “to act anew in the private and public worlds one inhabits” (p. 50). Curriculum as a verb moves beyond considering its goals, guidelines, and proposed outcomes. Instead, curriculum as lived experience means recognizing the stories, struggles, and identities that curriculum silences, praises, reinforces, and negotiates.

The concept of *currere* influenced other branches of curriculum studies, including the post-structural turn in the field. Kincheloe (1998), for example, proposed that *post-formal* thinking in relation to *currere* could produce new pedagogical commitments for teachers and students. He saw *currere* as meaning that “self and identity should be cultivated in relation to the learning process” (Kincheloe, 2013, p. 130) allowing an analysis of how identities and social positionings are constructed through “power discourses and political structures (p. 131). In his view, *currere* and post-formal thinking would enable

students to deconstruct their personal constructions of the purpose of their schooling; it induces men to expose the ways the privileged position of masculinity has shaped their self-images; it induces heterosexuals to refigure their identities vis-à-vis confrontation with the dynamics of heterosexism and sexual preference; it induces workers to reconsider the workplace and its social dynamics as profound influences on identity formation. The postmodern condition’s crisis of meaning and identity is also a crisis of thinking. As a culture, we have little idea how our identities are shaped by power relations and the impact of such a process on how we define intelligence. Post-formal thinking about thinking appropriates *currere*’s ideological disembedding, pushing cognition into the complexity of self-production. Transcending Piagetian formalism with its disembodied abstraction and its concern for disinterested procedure, post-formal thinking about thinking encourages a running meta-dialogue, a constant conversation with self (p. 132).

Kincheloe’s words here are indicative of how poststructural curriculum studies scholars worked alongside other attempts from the 70s, 80s and 90s to understand how identities were produced and reproduced.

Identity and curriculum: the influence of socio-cultural theorizing

Identity options emerged in the 2000s while the pace and intensity of thinking with curriculum and identities increased with new socio-cultural theorizing. Important for conceptualizing identity options and a lynchpin of the research in this vein is the concept of *funds of knowledge* (e.g., González et al., 2005). The concept was developed through an ethnographic project that invited teacher-researchers to learn about the household and community knowledges of Mexican, African American and American Indigenous children in the United States. The goal was to use this knowledge for responsive, *asset-oriented* (Heydon and Iannacci, 2008) curriculum-making. Visiting the neighborhoods where children lived and interviewing their families, the researchers studied “what households actually do and how they think about what they do” (González et al., 2005, p. 10). Funds of knowledge was based on the belief that “people are competent, they have knowledge, and their life experiences have given them that knowledge” (p. ix–x), a premise that was in direct opposition to a deficit-orientated curriculum that minoritized learners, their families, and communities (e.g., Shields et al., 2005). Buoyed by the theory of funds of knowledge, educators were poised to promote curricula that capitalized on what children knew and their community identities could be used for curriculum-making.

Growing out of funds of knowledge is the concept of *funds of identity* (e.g., Esteban-Guitart and Moll, 2014a). Combining cultural psychology with socio-cultural theories of learning, Esteban-Guitart and Moll (2014a) explained that “‘identity’ is not a thing, but a social construct vaguely referring to a vastly complex set of phenomena” (p. 32). They claimed that identity is part of people’s daily lives, something every person talks about and indexes to indicate who they are as they draw on categories such as gender, professional identity, and religious identity; identity is thus seen as an essential part of people’s self-expression and self-understanding. Identities too are lived, created in interactions between people, symbols, and artifacts in context. For Esteban-Guitart and Moll, identities are “social products, cultural devices, a kind of box of tools which can be used to define oneself” (p. 35). Rather than considering identity as a phenomenon that occurs exclusively in people’s minds, or a fixed trait, identity here is inextricably connected to culture, mediated, distributed among people, artifacts, contexts, and the like. People identify themselves always in relation to others, their known cultural worlds and social artifacts. Esteban-Guitart and Moll further explained that activities and artifacts such as songs and worship, become tools through which individuals make and express their identities: “Identity is in things as well as people In an important way, a person’s self can be viewed as a dynamic organization of various resources, socially, historically, and culturally created” (p. 37).

Funds of identity conceptualizes how people and communities come to build identities and express those identities based on what is available to them through their funds of knowledge and cultural capital (Esteban-Guitart and Moll, 2014b). Whereas language, religion, and geographic locations are part of funds of knowledge, when these elements become resources for self-identification, they become funds of identity. Funds of identity are unfixed; Esteban-Guitart and Moll (2014a) claimed that as people acquire life experiences, more funds of knowledge are available to them and, in turn, new resources for identifying themselves. Esteban-Guitart and Moll’s (2014b) theorizing of *lived experience* is central to identity. Lived experience, they expressed, is conditional since it emerges in the encounters between person and environment, previous experiences, and knowledges in contact with new possibilities that a social and cultural context offers over time. How a learner feels and understands the situations they live is their lived experience; it is an aggregation of internal and external factors. Esteban-Guitart and Moll (2014a) cataloged identity resources as follows: (a) “geographical funds of identity” (place, nationality); (b) “practical” (work or activity); (c) “cultural” (“national flags or social categories”); (d) “social” (“significant others such as relatives, friends”); (e) “institutional” (family, religion) (p. 38).

The premise of funds of knowledge in education works in parallel with funds of identity: by learning about and documenting students’ experiences, their funds of knowledge can be included in curricula and their funds of identity affirmed (Esteban-Guitart and Moll, 2014a). Esteban-Guitart and Moll (2014b) further suggested pedagogies for prioritizing expansive funds of identity. Like the multimodal learner and community-focused texts of identity texts (e.g., Cummins, 2006), Esteban-Guitart and Moll (2014a) called for pedagogies like the *significant circle strategy* in which the learner draws and/or writes in a circle what is important to them, such as family members, hobbies and objects. In all, Esteban-Guitart and Moll (2014b) encouraged educators to see learners’ funds of knowledge and identities as curricular resources and schools as spaces that reflect the community and the people who are part of it, bridging and valuing the different contexts that compose learners’ lives.

Funds of knowledge and identity are concepts that are like the aforementioned identity options. Both are founded on socio-cultural theory, prioritize the relationship between socio-cultural and semiotic contexts and the learner, and actively work against the minoritization of knowledges and languages. Moreover, the work of funds of knowledge and identity, like that of Cummins and Early’s (2011) identity texts and Heydon’s (2013) multimodal intergenerational curricula, considers how languages, modes, and out-of-school socio-cultural knowledge can be resources for school curricula and lead to the empowerment of people who might otherwise be constructed as pathological or deficient (e.g., Heydon and Iannacci, 2008).

Socio-material approaches to identities and curriculum

Most recently, socio-material theories and orientations have entered educational research, with major implications for conceptualizing curriculum and identity. One of these orientations is *posthumanities* which, according to Braidotti (2019), is an emergent field of study that grew in the contact zone between post-anthropocentrism and posthumanism, where the first offers a critique of a hierarchy of species in which humans are at the top and the second debunks the notion that the human is the “universal measure of all

things" (p. 32). The Anthropocene is what Haraway (2015) explained as the "immense irreversible destruction" (p. 160) of the planet. The era is also described by Braidotti (2019) as characterized by rapid technological developments and increased economic and social disparities. Education scholars engaged with ideas sympathetic to or directly announced as premised in posthumanities, come from a range of foci including literacy education (e.g., Hackett and Somerville, 2017; Kuby et al., 2019), Indigenous education (e.g., Jones and Hoskins, 2016; Tuck and McKenzie, 2015), and mathematics education (e.g., de Freitas, 2016). Each in its own way, counter to socio-cultural approaches just discussed, this scholarship de-centers learners as the focus of curriculum. Some have argued that this decentring is not a dismissal of learners; rather, moving the focus from the human provides opportunities to appreciate the constituents and movements of the time/space/matter in which learners are implicated (e.g., Kuby and Rucker, 2016), allowing for a questioning of how the entanglements that characterize education might better produce knowledge of how to live well together (Murrin, 2016). Indeed, the industrial products of traditional curriculum become profoundly upended through this movement. Finding the ability of any curricular system to predict and control knowledge and the creation of a particular kind of citizen a "fantasy" (Edwards, 2011, p. 39), posthumanities challenges the neoliberal projects of othering, in which the constituents of this planet (including the humans who are the students) are commodities for extraction and economic advancement (Tuhiwai Smith et al., 2018).

Posthumanities brings to the fore a new conversation where ethics is inseparable from ontology and epistemology (e.g., Barad, 2007). Barad (2007) described her approach to posthumanities as having to do with "responsibility and accountability for the entanglements 'we' help enact and what kinds of commitments 'we' are willing to take on, including commitments to 'ourselves' and who 'we' may become" (p. 382). In this sense, education scholars working with posthumanities understand that their practices cannot be dissociated from the world as they intra-act with all the human and non-human inhabitants that co-constitute it. Posthumanities ethics entail a project of breaking down ideas of universal experiences. In education, this can apply to the developmentalist idea of the universal child as well as social categories of identity that fall within simplistic binary oppositions such as boy/girl, black/white, high socio-economic standing/low socio-economic standing. Braidotti (2019) advocated instead for *situated knowledges*, which refers to the idea that political subjectivities and knowledges are always entangled with time and space, which makes each experience distinctive, ongoing, not universal. Thinking curriculum through this perspective attunes educators to the relationality of knowledge production and the local specificities that constitute materially and semiotically "the kind of knowing subjects currently constructed" (p. 34). This is one example of how posthumanities offer "a frame to understand the ongoing processes of becoming-subjects in our fast-changing times" (p. 34), without focusing exclusively on the human subject.

The focus of the identity conversation with the introduction of posthumanities shifts radically from human identity that comes from what is human-made, as in the case of socio-cultural approaches, to how subjectivities are co-produced through the kind of complex entanglements outlined above. Braidotti (2019) explained subjectivities as:

not restricted to bound individuals, but is rather a co-operative trans-species effort (Margulis and Sagan, 1995) that takes place transversally, in-between nature/technology; male/female; black/ white; local/global; present/past—in assemblages that flow across and displace the binaries. These in-between states defy the logic of the excluded middle and, although they allow an analytic function to the negative, they reject negativity and aim at the production of joyful or affirmative values and projects (Lloyd, 1996; Braidotti, 2011). Poststructuralism paved the way for this approach, but the posthuman turn materializes it and composes a new ontological framework of becoming-subjects (p. 33).

Developing ideas from Queer Theory, Braidotti (2019) rejected binary oppositions and fixed identities, forwarding the idea that being is a never ending, cooperative process of creation between humans and non-humans, and "within this worldview the posthuman subject emerges as multiple and inherently differentiated" (van der Zaag, 2016, p. 331). This insistence on difference is, again, not just ontological, but ethical.

Ethics has not, as we suggest earlier in this article, always been visible in discussions of curriculum. We saw in the early days of curriculum studies a major disavowal of identity—the person as a sentient entity with a history, a family, a story, was of no consequence to the curricular machine; the machine would make the right kind of citizen and implant the right kind of knowledge into this "faceless" (Aoki, 1993, p. 261) student. Subsequent waves of critically oriented theory into curriculum studies such as socio-cultural theory and feminist theory vehemently ascribed the face to the learner, emphasizing its relevance to what curriculum produced and who it favored. These faces were faces of asymmetrical power based in social and economic structures (e.g., Apple, 2008). Phenomenology of the day highlighted the face as also an internal face, produced through the experience of living curriculum; and the early poststructural movement in curriculum played a version of "a kind of intellectual version of the hokey-cokey" (Stronach and MacLure, 1997, p. 19) where identities could be multiple and unfixed, yet also related to critical readings of social structures and markers (e.g., consider Kincheloe and Pinar alongside each other). The ethico-onto-epistemological orientations of posthumanities scholarship create opportunities to see curriculum and identity in fresh and disruptive ways.

Erica Burman's (2021) *Developments: Child, Image, Nation* is an example of scholarship sympathetic to posthumanities that creates new resources for conceptualizing identities. Burman traced the connections between developmental psychology and economic development, claiming that ideas of progress from the global North are aligned with colonial, neoliberal agendas that decontextualize childhoods and aim to create manageable, universal subjects, much like in the early days of curriculum. Burman's focus is not identities, but her postdevelopmental theorizing is an important counterpoint to previous conceptualizations of identity. Her book, for example, considered subjectivities as they relate to developmental psychology's construction of the normal child, a construct which has influenced numerous curricula (e.g., Iannacci, 2019). In contrast, Burman (2021) eschewed notions of child

(and, in our extension, identity) that are autonomous, asking instead for “situated, nuanced ... narratives” (p. 32) of children and childhoods. A companion to a relational subject is the shaking of any claims to “authentic, unmediated exhibitions of inner subjectivities (whether others’ or their own)”; there are, Burman argued “limits of what one can claim to know, and the different knowledges that can be brought to bear in different contexts” (p. 57). These ideas have implications for thinking with any conceptualization of identity that is reliant on humans as singular, rationale beings who can fully know or design themselves or their identities.

There are times in her work when Burman (2021) addresses identity specifically and in so doing further ruptures links with old thought. One of these times was when Burman expressed the difficult roots of identity and the kind of identity categories that were suggested in some critical approaches to curriculum. To this point, Burman said,

the gender, class, and cultural relations—that privilege male over female, white over black, heterosexual over homosexual, middle over working class—are deeply implicated within the technological and colonial development of nineteenth-century Europe. Cultural analysts and philosophers have pointed out that one conceptual condition for all of this was the fixing of all these categories via the notion of “identity” (p. 159).

Burman was here again concerned with how identity, as a social marker, can be taken on as a psychological phenomenon and operate through a focus on the individual and a two-dimensional view between that individual and the social order.

The above is a complaint that resonates with Haraway’s (2016) advice that the Anthropocene (what she called the Chthulucene), is a time of deep relationships of all kinds which demands *making-with*, not *self-making*. Similarly, Ringrose and Renold (2016), writing about posthumanism and education, offered,

in Braidotti’s influential book *The Posthuman* (2013) she lays out her vision of posthuman feminism as that which “rebels” against identity politics and dominant categories of identity. Posthuman feminism goes beyond antihumanist critique (potestas) to act and move (potentia) (Ringrose and Renold, 2016, p. 26). Posthuman feminism incubates and injects lethal viruses to shake “the political economy of phallogocentrism and of anthropocentric humanism.” Braidotti specifically advocates that “posthuman feminists look for subversion not in counter-identity formations, but rather in pure dislocations of identities via the perversion of standardized patterns of sexualized, racialized and naturalized interaction” (Braidotti, 2013, p. 99). Evoking the famous Deleuzo-Guattarian phrase about bodily capacities, Braidotti (Braidotti, 2013) calls upon us to experiment with resistance and intensity in order to find out what “posthuman bodies can do” (p. 221).

But we ask what might it mean to dissolve the concept of identity and see what posthuman bodies can do in and through curriculum? And what is the ethico-onto-epistemology that accompanies this dissolution?

There are no firm answers to questions like these, and so any responses must *stay with the trouble* (Haraway, 2016), acknowledging, for example, the limitations, incommensurabilities, and aporia that accompany all related thinking. This staying with the trouble is itself an ethic. Witness Burman (2021) in her attempt to think with identity, the trouble with dualistic social categories, and the need to develop new lines of thought. Burman resourced the cyborg and cautioned against resourcing the cyborg:

There are clear difficulties in knowing how far to develop the cyborg metaphor. And at the outset there is the temptation to turn it into a subject, an identity, for this would recuperate the cyborg back into individualist psychology. (The fact that typically cyborgs are discussed only in the singular—“the” cyborg—bolsters this, as indeed do the many cultural representations that portray the cyborg as lonely, agonised, and longing to be, or to be like, a human.). These ideas become relevant here as a strategy to disturb psychological representations of subjectivity. For the cyborg resists the trappings of subjectivity and identification (Gordo López and Parker, 1999) and so exposes their limitations (p. 218).

Thinking with the cyborg is a troubled activity, but one that is productive in its trouble. It exposes some of the limitations of known approaches to identity (along with representation and subjectivity) and might be suggestive of paths forward. For instance, in thinking with the cyborg, Burman said, “the cyborg has no stable identity, and does not organise with others on the basis of similarity. Rather, its communities are temporary strategic alliances or affiliations organised around specific goals” (p. 217). In so saying, Burman evoked a suggestion offered by Ringrose and Renold (2016) to the difficulties of identity in Braidotti (2013).

The orientations of posthumanities allow for a sitting with the unease of incommensurabilities with ethics at the core. Ringrose and Renold (2016) suggested some of the constraints of Braidotti’s (2013) rejection of identity while simultaneously loving her. They also brought into view a contemporary version of the hokey-cokey, this one an avowedly critically oriented posthumanities. Ringrose and Renold (2016), for example, said:

Despite our longstanding love affair with Braidotti (see Renold and Ringrose, 2011 and forthcoming) we find her call for “pure dislocations of identity” utopic and problematic. Challenging simplistic identity politics around universal womanhood or girlhood has never meant throwing out or simply blowing up identity categories. Critically engaging with strategic essentialism in the context of everyday political activism has proven more useful (Spivak, 1990). Not satisfied with abstract treatises on what posthuman feminism should be, we want to use the important conceptual tools of posthumanism to think methodologically about the processes involved in feminist “becomings” through our empirical research on feminist groupings and politics in secondary schools (p. 221).

Burman's (2021) description of the cyborg's "strategic alliances" (p. 217) seem to connect to Ringrose and Renold's (2016) raising of *strategic essentialism* which in its classic critical, postcolonial sense referred to the "strategic use of essentialism" (Danius et al., 1993, p. 35) by the *subaltern* (Spivak, 1988) with Spivak emphasizing the strategic part of the term (and even wanting to abandon the term because of her readers' over-reliance on the essentialism part) (Danius et al., 1993). There is no resolution to the conundrum of identities as problematic, identities as politically useful, identities as stultifying, identities as a needed heuristic, and one of the affordances of thinking with identities in posthumanities is that they can be all these things at the same time and more.

Posthuman curriculum asks educators to think relationally about what composes curriculum and how curriculum produces networks of effects. Curriculum emerges from and generates relations between humans and non-humans (computer, classroom materials, learners, teachers, knowledges, places, time). Identities and learning are entangled in this web of relations and are not neutral. Curriculum choices become complex ethical commitments. Posthumanities in education requires a shift away from the view of humans as saviors or sources of power. Curriculum history has acknowledged the human as a "normative category" (Braidotti, 2019, p. 35), the point of reference of all other categories and divisions. Posthumanities complexifies the human category and makes it impossible to see humans as a point of reference for everything else. Curriculum must instead notice the interdependence and importance of all beings and becomings. Braidotti (2019) explained that posthumanities "offers a spectrum through which we can capture the complexity of ongoing processes of subject formation. In other words, it enables subtler and more complex analyses of powers and discourses" (pp. 35–36) promoting "complexity, embodied and embedded diversity and multiple becomings" (p. 37).

Concluding thoughts

In our examination of the treatment of identity theorizing across curriculum, we have found that the concept of identity options has numerous contributions to make to curriculum thought and practice. Identity options, as we have suggested, for instance, signals many things: the limits of technologies of curriculum that would be built without consideration for the learner; the need for epistemic and ontological diversity in curriculum; how curricula can colonize, minoritize and promote particular kinds of citizens; and the ethical requirement for curricula that promote expansive identity options for learners.

The concept of identity options is closely connected to lived curricula, with both forwarding awareness that learners experience and co-produce classroom curricula in potentially infinite ways, hence exploding the myth that programmatic curriculum can ever be enacted without alteration or be singularly apprehended.

Identity options, as a concept, owes an intellectual debt of gratitude to movements connected to the reconceptualization of curriculum, and has its lineages in related forms of critical, socio-cultural theorizing. Recent thinking oriented toward posthumanities has demanded that curriculum scholars rethink identity options and identity more generally to consider the constraints of human-centric thinking.

Origins of cross-cultural narrative inquiry

My experience of cross-cultural narrative inquiry was originated from my explorations during my master's program of studies at OISE/University of Toronto on immigrant education by understanding language, culture, learning, and teaching as a social process; by examining the political and social context of the education of language minority students; and by looking into the interconnectedness of language, culture, and identity. In my doctoral program, I studied narrative approaches to curriculum, teacher development, and research with F. Michael Connelly, where narrative, as phenomenon, as method, and as a form of representation is an approach about how people experience their lives, how they interact with others, how they shape and are shaped by the contexts in which they live and work. I explored a wide array of works related to narrative such as currere/feminist autobiography in the works of William Pinar and Madeleine Grumet in 1980s, 1990s, and 2000s; Janet Miller's work on teachers' auto/biography in 1980s, 1990s, and 2000s; bell hook's work in 1990s and 2000s; Richard Butt and Daniel Raymond's works on auto/biographical studies and collaborative autobiography, teachers thinking, and teacher's voice in 1980s and 1990s; Freema Elbaz's works on teacher thinking and personal practical knowledge in 1980s, 1990s, and 2000s; F. Michael Connelly and D. Jean Clandinin's works on teacher's personal practical knowledge, professional landscape, and narrative inquiry in 1980s, 1990s, 2000s; William Schubert's work on curriculum books, teacher practice, and teacher knowledge in 1980s, 1990s, 2000s; William Ayers' work on teacher practice, teacher education, teachers auto/biography, and social justice in 1980s, 1990s, 2000s; William Schubert and William Ayers' work on teacher lore/learning from one's own experience in 1992; Ivor F. Goodson and Andy Hargreave's work on teachers' professional lives in 1996; Marilyn Cochran-Smith & Susan L. Lytle's work on inside/out/teacher research and knowledge in 1993; Donald Schön's work on reflective turn/case studies in and on educational practice in 1991; Tom Russell & Hugh Munby's work on teachers as reflective practitioners and the role of experience in developing teachers' professional knowledge in 1990s, 1990s, and 2000s. However, the above-mentioned narrative approaches do not help capture the cross-cultural aspects of life.

I then turn to cross-cultural narrative inquiry which humanizes research that is philosophically compatible with cross-cultural lives and identities central to multiculturalism. I became involved in a Social Sciences and Humanities Research Council of Canada (SSHRC) funded long-term research program on teacher knowledge (1991–1998). I was a participant observer in a large urban adult ESL Center and conducted interviews with librarians, administrators, lead teachers, classroom teachers, and adult ESL learners while I was teaching Mandarin to Grade 6–12 public school children and English as a Second Language to immigrant adults and children, developed my understanding of the complexity of immigrant lives. I was also involved in other research with nursing educators and immigrant nurses, which helped further develop my research in cross-cultural inquiry of multicultural/multilingual education.

Cross-cultural narrative inquiry explores experience by bringing cross-cultural personal experience to bear on inquiry, seeing research as having autobiographical roots, as connected to, rather than disconnected from cross-cultural life; by thinking narratively, seeing cross-cultural experience as the starting point of inquiry, as fluid and changing rather than fixed, as contextualized rather than decontextualized; by being in the midst of cross-cultural lives, seeing research as long-term, passionate involvement in daily lives of participants, rather than short-term, in and out, detached observation; and by making meaning of cross-cultural experience in

relationship, rather than making meaning in isolation (Phillion and He, 2001, 2008; He and Phillion, 2008). Cross-cultural narrative inquiry, an approach that humanizes research, focuses on cross-cultural experience.

Creating a composite auto/biographical narrative method to study the bilingual/bicultural and multilingual/multicultural experience

My doctoral research was a study of cross-cultural identity development of three Chinese women teachers as they moved back and forth between Eastern and Western landscapes, cultures, and languages (He, 1998, 1999, 2003). Shiao, Wei, and Ming Fang, three participants in the study, were born during the Anti-Rightist Movement and the Great Leap Forward in the late 1950s, grew up during the Cultural Revolution (1966–1976), were exposed to foreign cultures and pursued undergraduate studies in Chinese universities (1978–1989) since the beginning of China's open door policy (1978–1989), pursued graduate studies in Canada (1988–1998), and moved to immigrant education (Shiao), cosmetic business (Wei), and North American academe (Ming Fang). As we moved between languages and cultures, the East and the West, the cultural, educational, and language strangeness we experienced was further complicated by rapid changes occurred in both landscapes. We did not feel at home in either place. Our foreignness and at-homeness in both landscapes were interchangeable, a phenomenon which characterizes our cross-cultural lives. I struggled to come to grips with new ways of thinking to bridge our lives in China, lives in Canada, lives in North American academy, and lives in-between. I started this life-based narrative inquiry, situated between non-fiction, fiction and academic discourses, with a hope to create possibilities for establishing a linkage between cross-cultural lives and identities, cross-cultural teacher education and curriculum studies in multicultural/multilingual contexts.

As my participants and I continued our inquiry of cross-cultural lives, we felt that our identities were threatened by telling our stories in public. Due to political reasons, I experimented with a composite auto/biographic narrative method to protect our identities and to capture the complexity of such identities (He, 1998, 1999, 2003). This method captured the essence of four bodies of literature in research in social sciences: auto/biography; fiction; narrative or closely related to narrative research in anthropology, ethnography, psychology, psychotherapy, psychiatry, theology, organizational theory, and social sciences in general; and narrative research in education. Other narrative works from people in different educational fields were also referred to such as teacher education; teaching and learning; writing; science education; curriculum studies; language teacher knowledge; educational psychology; Black feminist studies; multicultural teacher education, philosophy, and educational philosophy. Connelly and Clandinin (e.g., Clandinin and Connelly, 2000) pioneered narrative inquiry in the field of education and they have the longest sustained program of narrative research. Their work tremendously influenced my early work on cross-cultural narrative inquiry.

My participants and I worked through four procedures of my composite auto/biographical method. (1) We fictionalized our identities in the research text. My participants used pseudonyms of their choice. Their backgrounds were fictionalized according to their preference. We used the fictionalized first persona to tell our real stories. In my case, since my name and background were known to the reader, some of my stories were told through my participants with their permission. (2) We told and retold our stories. (3) We went back to our stories, relocated stories in a particular persona's voice, and developed a joint interpretation. The interpretations included agreement, disagreement, and puzzlement. (4) We went back to our stories and interpretations, and confirmed, or altered them. My participants and I, for example, tell stories of the Cultural Revolution (1966–1976) in a "stream of consciousness" narrative collage. This technique in writing with fragments of sentences ending in dots rather than complete sentences captures the shifting and evolving aspects of our displaced and disrupted lives. Three passionate and emotional voices tell stories within the same time span and across different spaces and settings as if watching a film with three pictured stories on the same screen. This extends a first person, singular account of narrative plot and temporality to a collective voice which represents stories located within a larger historical, socio-political, cultural, and linguistic context. Utilizing collage storytelling techniques with changing voices and fonts in the text helps capture a narrative unity out of fragments of stories by breaking the limits of time, space, and place. The cross-cultural narrative inquiry method moves beyond traditional narrative writing discourse and research boundaries and tells hidden and silenced narratives of suppressed and underrepresented groups to counter the preconceived metanarrative represented in the mainstream research literature that has often portrayed these groups as deficient and inferior. By telling counter stories, researchers begin to be aware of the importance of commitment to equity and social justice, and to recognize their obligation to link inquiry to social and educational change.

Representing bilingual and bicultural lives and identities

Along with my experiment with composite auto/biographical narrative method, I explore the bilingual and bicultural narrative representation of cross-cultural lives and identities (He, 1999, 2003). I derive the forms of narration from the storytelling styles of my participants instead of imposing my style upon them. For instance, when I tell the stories from my participants, I purposely use their words and expressions to reveal their cultural, linguistic, musical, or scientific backgrounds. Instead of polishing the interview and conversation transcripts, I deliberately allow orality (i.e., keeping in the realm of speech with its characteristic tones, pauses, and rhetorical transitions) to flow through while theorizing those stories in the left-hand column or in italics. As a bilingual and bicultural narrative researcher, I incorporate our Chinese voice into the text without losing the flow of English discourse. When I have difficulty in finding the English equivalent for specific Chinese words, phrases, slogans, and sentences, I mark them with

quotations and put the English translation and the Chinese in parentheses to satisfy both English and Chinese readers and to compensate for the loss of meaning in translation. However, in order to keep the flavor of both languages, I am caught in conflicts. Some of the expressions and metaphors convey different meaning depending on the language being used. I have to break those barriers to develop a new meaning based on both languages. If the conflict is irresolvable, an additional explanation is provided. It is crucial to develop a bilingual and bicultural methodology to research on bicultural lives and identities. Although my research has been conducted in Chinese and English only, I believe that it has implications for other bilingual and bicultural inquiries in the United States and other international contexts.

Using metaphors to identify research themes and understand cross-cultural experiences

As I collect stories from myself and my participants, I have found that my participants and I tend to narrate our experiences of acculturation and enculturation in China and Canada through metaphors such as journey metaphors, spatial metaphors, landscape metaphors, cultural metaphors including deceptional metaphor which conveys a philosophical truth through a fallacy as well as musical metaphors, and personal metaphors. As our stories of identity development and cultural transformation unfold, we realize that our modes of learning and ways of expressing ourselves are closely related to Chinese language and culture, which is strongly metaphorically oriented. The way metaphors developed implicitly from our cultural experiences helps explicitly portray the personal and professional identity development and knowledge transformation in our acculturation and enculturation processes in China and Canada. Thus I employ metaphor as both phenomenon (embodied in stories) and method (identifying stories) to explore the acculturation and enculturation processes of teachers and learners in China and Canada. I use a river metaphor to explore three phases in my life and the lives of my participants: our lives along the Yangtze River and the Yellow River before, during, and after the Cultural Revolution in China with multiple cultural movements; our lives in the cross-cultural flow in China and Canada; and our lives in the multicultural flow of the North American academy (He, 2002a, b, c). Special attention is paid to the relationship between our cross-cultural experience in China and Canada, the cultural impact of our move to Canada, and our experience of learning to become North Americans, a cultural process no less of an upheaval or displacement than the Cultural Revolution. I also use the river metaphor to create a new conception of multiculturalism perceiving different cultures as rivers running together to create sediment for a multicultural delta where lives of various cultural, ethnic, and linguistic groups merge with their own currents. This work is situated between nonfiction, fiction, and academic discourses. It is written in a way that is accessible to a large audience directly and indirectly involved in cross-cultural/bilingual/bicultural/multilingual/multicultural education, and transnational/diasporic studies. I see my work as fitting into an evolving, increasingly important, paradigm in the field of educational research on issues of language, culture, identity, and power in relation to bilingual/bicultural/multilingual/multicultural education and exile/in-between curriculum for dislocated, disenfranchised, and underrepresented individuals and groups.

Tales in words and tales on canvas—telling stories through arts and poetry

As I write about our stories in English, I encountered one of the major concerns over the generalizability of our stories of cross-cultural lives and identity development. Our narratives might strike the reader as being too individual, subjective, idiosyncratic, and anecdotal, and might be perceived to be noncomparable, non-generalizable, and non-scientific. I then discover a parallel way of storytelling through my collaboration with You Sha Liu, a Chinese woman artist. You Sha shares her cross-cultural life stories through painting, while my participants and I tell our stories in words. You Sha and I come together to make sense of our cross-cultural lives and to represent those stories through tales in words and tales on canvas (He, 1999, 2003). Between the lines of the text and colors on the canvases, our actions are transformed into imagination while imagination is converted into actions. The result of collaboration is a blend of narrative aesthetics: fiction ~ fact, dream ~ reality, theory ~ practice, retrospection ~ imagination, auto/biography ~ portraits. In this juxtaposition of narrative “onstage,” point of views have changed, characters shifted, sequences of events vanished, images clashed, and realms of narrative discourse collided. We also find that both in poetry and in the visual arts, the temporal, spatial, perceptual, social, or moral entities are not fixed but evolving with our inquiries of identities and lives in-between landscapes. I struggle to maintain the consistency of tenses in reflections upon past experiences. In Chinese there is much more freedom in tenses. We use variations of the third person all the time and sometimes we even omit tenses altogether. In English, however, there are specific rules for the proper use of verbs as they relate to different time periods. As a lifelong second language learner, I constantly struggle for the proper use of prepositions and articles in English. As I translate our stories and emotions into the text, poetry helps capture passions, emotions, and imaginations aroused by our complicated experiences without being inhibited by tenses, prepositions, and articles.

Narrative and experience in multicultural education

I also engaged in an edited book project, *Narrative and Experience in Multicultural Education* (Phillion et al., 2005). This chapter explores the potential that narrative and experiential approaches have for understanding issues of language, culture, identity,

and power related to multiculturalism in education. The research featured in the book reflects a critical way of understanding the nuances of multicultural life and the complexity of multicultural issues in education. The studies focus on the lives in schools, families, and communities. The particular quality of the work featured in this book that distinguishes it from other work in multicultural education is the emphasis on experience, understanding of experience, and the transformation of this understanding into social and educational change.

Using life based literary narratives in multicultural teacher education

I have been teaching in a predominantly White institution since 1998. As an educator of both preservice and in-service teacher education students, one of the major challenges is how to prepare White teachers in rural areas of the United States to meet the needs of increasingly diverse populations of students. Drawing upon the work of Martha Nussbaum (1997) on narrative imagination and Maxine Greene (1995) on literary imagination, I collaborate with JoAnn Phillion to engage our students in life based literary texts such as memoirs, autobiographies, and novels that focus on the daily experiences of diverse families, parents, students and teachers (Phillion and He, 2004). For Nussbaum (1997), narrative imagination means “the ability to think what it might be like to be in the shoes of a person different from oneself, to be an intelligent reader of that person’s story, and to understand the emotion and wishes and desires that someone so placed might have” (pp. 10–11). For Greene (1995), “[Literary] imagination is what, above all, makes empathy possible. It is what enables us to cross the empty spaces between ourselves and those we teachers have called other over the years” (p. 3).

In our teacher education courses, students first read Nussbaum’s (1997) *Cultivating Humanity: A Classical Defense of Reform in Liberal Education* and study the key concepts of narrative imagination, self-examination, and world citizenship. In the process of reading life based literary narratives and reflecting on their experiences, students develop narrative imagination (the ability to actively empathize with others), and engage in self-examination (the ability to critically examine ones’ traditions, beliefs and values), enabling them to begin to understand themselves as world citizens (the ability to see themselves as members of not only a local community, but also a world community) (Nussbaum, 1997). Our attempt is to engage our students fully in a quest “to cultivate their humanity ... to see themselves not simply as citizens of some local region, or group, but also, and above all, as human beings bound to other human beings by ties of recognition and concern” (Nussbaum, 1997, p. 10). In developing a sense of “world citizenship,” students learn to step out of their comfort zone, to challenge assumptions and question taken-for-granted truths, to experience differences, and to make connections between the worlds they live in and the worlds of others. They also read Greene (1995) *Releasing Imagination: Essays on Education, the Arts, and Social Change* and explore ideas of literary imagination, creating possibilities, and expanding community. The key concepts of Nussbaum and Greene provide the guiding philosophical framework for the courses.

We also draw upon a wide array of works on multicultural education such as culturally responsive/relevant/sustaining curriculum and pedagogy (Gay, 2000/2018; Ladson-Billings, 1994/2009, 2021; Paris and Alim, 2017), funds of knowledge (González et al., 2005), cultural modeling (Lee, 1996/2009), and third space (Gutiérrez, 2008; Gutiérrez et al., 1999). These works inspire teachers in schools to work with other teachers, administrators, parents, students, community workers, policy makers, and other educational workers to engage in critical reflections and dialogues; exemplify democracy for the common good; resist oppression, suppression, and repression; decolonize space and place; teach and learn toward freedom; “hope radically, imagine creatively, and act inspirationally” (Ball et al., 2017, p. 2); transgress epistemological, socio-political, cultural, and linguistic borders to become the light in troubling times; and invent a landscape of education for cultural and linguistic diversity where creative and worthwhile culturally sustaining (Paris and Alim, 2017) learning and teaching make the impossible possible in the increasingly multicultural/multiethnic/multilingual/multiracial world.

Then we read life based literary narratives such as Patrick Chamoiseau’s *School Days* (1994), Eva Hoffman’s *Lost in Translation* (1989), Toni Morrison’s *The Bluest Eye* (1970), and Maxine Hong Kingston’s *Woman Warrior* (1975). Our teachers are also encouraged to read autobiographical work such as Michele Foster’s (1997) *Black Teachers on Teaching* and Vivian Paley’s (1979) *White Teacher*; narrative inquiry research such as Chris Carger’s (1996) *Of Borders and Dreams: A Mexican American Experience of Urban Education* and Ming Fang He’s (2003) *A River Forever Flowing: Cross-Cultural Lives and Identities in the Multicultural Landscape*; and ethnographies such as Chritina Igoa’s (1995) *The Inner World of the Immigrant Child*, Lourdes Diaz Soto’s (1997) *Language, Culture, and Power: Bilingual Families and the Struggle for Quality Education*, and Guadalupe Valdés *Con Respeto: Bridging the Distances Between Culturally Diverse Families and Schools* (1996) and *Learning and Not Learning English: Latino Students in American Schools* (2001).

As our particular focus in multiculturalism is on language, culture and identity, we primarily use life based literary narratives written by immigrants of their experiences in a new land, and by minorities living in mainstream cultures (e.g., Anzaldúa, 1987; Blaise, 1993; Chamoiseau, 1994; Cisneros, 1994; Cowan, 1982; Crow Dog and Erdoes, 1990; Dorfman, 1998; Firmat, 1994; Hoffman, 1989; Kaplan, 1993; Kingston, 1975; Melanson, 1999; Rodríguez, 1982; Santiago, 1993). The purpose of choosing these narratives is to engage our students in the lives of others in dramatically different environments, and to feel how the characters struggle with new languages, cultures, and identities. As students are enveloped in these lives, we encourage them to reflect on their experiences, to recognize differences between their lives and the lives of the characters, to imagine what it would be like to live the life of the characters, and to envision what they would do if they had students with similar experiences as the characters.

In conjunction with reading life based literary narratives, autobiographies, narrative inquiries, and ethnographies which explore the experience of people different than themselves, we encourage our pre-service and in-service teachers to critically examine

themselves by composing autobiographical papers in which they reflect on their backgrounds and experiences, critically examine their values and beliefs to develop understanding of the ways in which their personal histories, cultures, and experiences affect who they were, how they become who they are, how they interact with others, and how they perceive the world. We encourage our teachers to compose narrative imagination papers where they reflect on a life based literary narrative and explore how it develops their ability to see how they are connected to others and to empathize with others; and a collaborative project in which students work together to extend their understanding of multicultural issues and to explore possibilities for changes in their classrooms, schools, and communities.

The focus is on the power of narrative to assist our students to increase knowledge of ways diverse students experience the world both inside and outside schools and classrooms, to make sense of lived worlds, to see themselves in the stories of others, to learn to listen to and hear the stories of others, to enter the realities of their lives often dramatically different than their own, not through abstract reasoning, but through developing their emotions and empathic understanding. We feel that in recognizing themselves as connected to all human beings, devoted to respect for difference, committed to equality and social justice, our students will see themselves as agents of much needed change in schools, societies, and other spaces and places.

Research on the education of Asian American immigrant students in schools/families/communities

The US Census 2020 reported six major race categories: White, Black or African American, American Indian or Alaskan Native, Asian, Native Hawaiian or other Pacific Islander, and other races. By 2020 of the total US population (331.9 million), 20.6 million people (6.2%) are identified as Asian, Native Hawaiian or other Pacific Islander. Of 44.9 million immigrants in the United States [13.7% of the total population (331.9 million)], 31% were Asian (14.1 million) (US Census Bureau, 2020). Asia is the second-largest region of birth for US immigrants, after the Americas, and since 2013 India and China have been the leading origin countries, displacing Mexico. Arrivals from Asia are projected to become the largest foreign-born group by 2055 surpassing Latinos as the largest group immigrating into the US (US Census Bureau, 2020). Asian immigrants have tripled over the past three decades representing the fastest-growing population of newcomers to the US, with higher levels of income and educational achievement than native-born Whites. Nevertheless, historically Asians have been the object of racist and nativist US legislation and policies relating to immigration, naturalization, civil and linguistic rights, and full access to education, including, *inter alia*, the Chinese Exclusion Act, Executive Order 9066, and *Lau v. Nichols* (Pew Research Center, 2022; Spring, 2016; Takaki, 1993). Asians are often *orientalized* (Saïd, 1979) as rote learning oriented and submissive learners, exotic others, or monolithic model minorities in times of peace and economic security, and vilified in times of war, economic adversity, and, now, zoonotic viral pandemics; and the cycle of perceived threat followed by xenophobic rhetoric and policy response continues with the rise in anti-Asian hate crimes in the wake of the COVID-19 pandemic and attempts to reverse the overrepresentation of Asian students at highly selective universities.

Further, the linguistic heritage, cultural knowledge, and experience Asian immigrants and their children bring to schools are often ignored or overlooked. The ethnic and cultural diversity within Asian and Pacific American groups is often obscured and ignored in mainstream scholarship. Asian and Pacific Americans are either excluded entirely from studies that focus on people of color or compared with European Americans and other minorities. One of the major reasons supporting the exclusion of Asian American and Asian Canadian students from the dominant discourse in education is “the stereotype that Asians do not have any problems (i.e., they are model minorities)” (Lee, 1996/2009, p. 5). The model minority myth masks struggles and difficulties Asian students face, perpetuates resentment and hostility from members of the majority and other minority groups, and bolsters crimes being committed against Asians. Many researchers call for attention to the needs of Asian students who are by and large neglected in educational policy making in terms of funding programs, services and educational resources. This relative absence from discourse in educational policy and practice, despite their growing presence in schools and societies (Park et al., 2001, 2003), are major reasons for developing more studies on Asian American immigrant students.

I have been engaged in a study in Savannah, Georgia for more than 15 years to explore how Chinese immigrant families and communities work with schools to facilitate their children’s academic success while maintaining their cultural and language heritage within diversities among minorities and other ethnic groups in the US South. This research project is part of a long-term program of research on language, culture, identity, and power in relation to bilingual/bicultural/biracial education, multilingual/multicultural/multiracial education, and cross-cultural curriculum studies and teacher education. It *builds on* my cross-cultural experiences in China, Hong Kong/China, Canada and the USA, and my ongoing cross-cultural educational research. It *extends* my previous cross-cultural narrative study of the identity development and cultural transformation of immigrant Chinese women teachers (He, 1998, 2003) *to an inquiry into* the impact of immigrant’s language, culture, and identity development on school-community relations and their bearing on immigrant children’s school success in an increasingly diversified society. This research links with significant documentary study, oral history research, memoir, ethnographic and narrative work done with immigrant families and children. This research illuminates silenced stories of Asian American families and children who are often neglected in educational policy making in terms of funding programs, services, and educational resources. Due to the fact that Asian immigrants are double-marginalized—they do not fit in the mainstream, dominant discourse nor do they fit in marginalized minority discourse, I inquire into Asian immigrants’ dilemmas, tensions, contradictions, and advantages associated with their lives in the East, in the West, and in-between.

Activist practitioner inquiry into the life in schools/families/communities in the US South

My cross-cultural narrative research and scholarship thrive upon my teaching and doctoral student supervision. I have established and sponsored a doctoral research seminar called *Works-In-Progress* where a group of faculty members and doctoral students gather regularly to invigorate discussions and conversations on current issues on dissertation work and educational research. An inquiry-oriented philosophy permeates all aspects of *Works-In-Progress*. I encourage doctoral students to perceive their dissertation work as a quest for possibilities for quality education in an increasingly expanding democratic society. I invite them to perceive this quest directly connected to their personal and professional concerns, research interests, and inquiries. I encourage them to bring in their personal/professional experience and practical knowledge to inform their research while moving beyond certain boundaries in their ways of thinking about, looking at, and writing about their research. I invite them to search for culturally relevant inquiries to locate research within complex social, cultural, historical, and linguistic contexts. I also invite them to create bridges between theory and practice, between worlds other than their own, to see themselves in the stories of others. I encourage students to be sensitive to the emotional aspects of language, cultural, and political concerns of their participants. I encourage them to understand, synthesize, analyze, and criticize others' theories of educational inquiries to develop their own through their dissertation work. I invite them to join the efforts of building a research community where diverse voices are heard, diverse ways of doing research appreciated, and diverse challenges initiated.

I invite them to keep asking themselves the questions: What kinds of educational research do we need to enhance democracy and social justice while advancing the knowledge that will make a difference in people's lives? What are the more pressing educational and social problems of our time we should address in our research? How do we position ourselves as educational researchers to help reinvigorate the discourse and the investment in the public good by offering research and scholarship that directly look at education and the public? How do people in schools, communities, and societies think and understand the ways educational research works? In which ways can we deeply engage ourselves in research that serves the public good but not merely our own interests? What role can and do education researchers play in challenging the reform efforts to live up to the standard of working in the public interest? *Works-In-Progress* generates some outstanding social justice-oriented dissertation work. Some of these social justice-oriented research have been and will continue to be published in academic outlets, and have been transformed into positive changes in institutions, schools, communities, and societies.

Building upon my teaching and doctoral student supervision, I have been developing a program of research with a particular focus on activist practitioner inquiry/research for social justice that explores life in schools, families, and communities in the US South (He and Ross, 2013; He et al., 2015). I co-edit a book series with Information Age Publishing, *Research for Social Justice*, which features educational research that connects the personal with the political, the theoretical with the practical, and inquiry with social change. The first book in this series, *Research for Social Justice: Personal ~ Passionate ~ Participatory Inquiry* (He and Phillion, 2008) features exemplary social justice work done by my advanced doctoral students and those of JoAnn Phillion. These inquiries demonstrate three distinct qualities. Each is personal, compelled by values and experiences researchers bring to the work. Each is passionate, grounded in a commitment to social justice concerns of people and places under consideration. Each is participatory, built on long term, heart-felt engagement, and shared efforts. The principal aspect of the inquiries featured in the book series that distinguishes it from others is that researchers are not detached observers, nor putatively objective recorders, but active participants in schools, families, and communities. Researchers have explicit research agendas that focus on equity, equality, and social justice. Rather than aiming solely at traditional educational research outcomes, positive social and educational change is the focal outcome of inquiry. The researchers are diverse and their inquiries are far ranging in terms of content, people and geographic locations studied. These studies reflect new and exciting ways of researching and representing experience of the disenfranchised, underrepresented, and invisible groups, and challenge stereotyped or deficit-oriented perspectives on these groups. This book series inspires pre-service and in-service teachers, educators, educational researchers, administrators, and educational policy makers to commit to the enactment of educational and social change that fosters equity, equality, and social justice.

I continue to create academic outlets to feature the cutting-edge work of diverse curriculum scholars, particularly those of my doctoral students who engage in social justice-oriented research and make positive social and educational changes in schools, communities, and societies. These social justice-oriented works focus on the power of counter narrative as a means to contest the official or meta narrative that often portrays disenfranchised individuals and groups as deficient and inferior. The counter narratives challenge traditional ways of engaging in and interpreting curriculum research and affirm the significance of curriculum inquiry as a form of liberatory or radical democratic practice. The counter narratives help tell silenced and neglected stories of experience of repressions, suppressions, and subjugations, stereotypes of Southern women, Blacks, and other disenfranchised individuals and groups; encourage examination of the force of slavery, racism, sexism, classism, religious repression and other forms of oppression and suppressions on the life and curriculum in schools, neighborhoods, and communities in the South; and promote a more equitable human condition that embodies cultural, linguistic, and ecological diversity and plurality of identities of individuals, groups, tribes, and societies that are conducive to the flourishing of creative capacities that invigorate intellectual, emotional, moral, and spiritual existence for all.

Research on the education of disenfranchised individuals and groups in Hong Kong and Mainland China

I have extended my research on language, culture, identity, and power in relation to bilingual/bicultural/biracial and multilingual/multicultural/multiracial education, and cross-cultural curriculum studies and teacher education in Canada and the United States to other international contexts such as Hong Kong and Mainland China where I have been enaging in two large scale research programs of study on minority and disenfranchised groups (He and Yu, 2017). Due to COVID-19, my research on the education of minority and disenfranchised individuals and groups in Hong Kong and Mainland China was delayed. This line of inquiry is exciting and challenging due to lack of concerns and actions on the education of these groups in history. I strive to work with multi-ethnic teacher-scholars, researchers, and practitioners to develop programs of research in which cross-cultural narrative inquiries are used to explore the life of schools, families, and communities to foster equity, equality, and social justice in Hong Kong, Mainland China, and other countries in Asia.

East meets west in curriculum studies

I am actively engaged in research in-between the Eastern and Western philosophy, curriculum, and pedagogy in education with a particular focus on Confucius, John Dewey, Tsunesaburo Makiguchi, Daisaku Ikeda, Weiming Tu, Martha Nussbaum, and Edward Saïd. I have been developing cross-cultural, bilingual/bicultural, and experiential approaches to curriculum, teaching, learning, and research in relation to bilingual/bicultural/biracial education and multilingual/multicultural/multiracial education, particularly the education of dislocated/exile/in-between, disenfranchised, and underrepresented individuals and groups. I particularly explore an East ~ West epistemological convergence of embodied democracy in education through cultural humanism illuminated in five main themes in the works of John Dewey (1859–1952), Confucius (551–479 BC), Ikeda Daisaku (b. 1928), and Tsunesaburo Makiguchi (1871–1944): *human-nature interconnection, self-cultivation, value creation, associated living, and joy of learning/happiness of living* (He, 2016). The cultural humanism, embedded in languages and cultures, flourishes with the ideal of embodied democracy that aims to educate for creative, harmonious, associative, joyful, and worthwhile living (e.g., Schubert, 2009a, b) for all in an increasingly diversified, complicated, and contested world.

The shared perspectives of Confucius, Ikeda, Makiguchi, and Dewey on cultural humanism, which transcend languages, cultures, and histories, create an East ~ West epistemological convergence of embodied democracy. In the midst of obstacles and challenges, I imagine cultivation of an East ~ West convergence of embodied democracy in education that fuses Confucianism, Makiguchianism, Ikedanism, Deweyanism, and philosophies from other Eastern and Western civilizations to counter globalization, standardization, and accountability; economic, racial, cultural-linguistic, social, gender and environmental injustice, acquisitiveness, and dislocation; and all forms of suppressions, repressions, and oppressions. Such a divergent East ~ West convergence of embodied democracy illuminated in cultural humanism in the works of Makiguchi, Ikeda, Confucius, and Dewey revitalizes human-nature interconnectedness, self-cultivation, value creation, associated living, and joy of learning/happiness of living, releases cross-cultural imagination, indigenizes Makiguchian, Ikedan, Confucius, and Deweyan educational ideals and philosophical traditions toward freedom and justice, cultivates humanity, and invigorates love, justice, and education for a better human condition for all (Schubert, 2009a).

Exile pedagogy/curriculum and teaching in-between

My cross-cultural narrative inquiry leads to my exploration of exile pedagogy, exile curriculum, and teaching in-between. I draw upon the works of Homi Bhabha on *location of culture* (1994) and *culture's in-between* (1996/2008); Gilles Deleuze and Félix Guattari (1972, 1980, 1991) on *rhizome, interbeing, intermezzo, multiplicity, and line of flight*; M. M. Bakhtin (1981) on *double-voiced, double accented, and double languaged hybrid*; Ted Aoki (2005a, b) on *teaching as indwelling between curriculum worlds*; Edward Saïd on *interstiti spaces and exile*; and Ming Fang He on *teaching, learning, and living in-between* (2003, 2006), *exile pedagogy—teaching in-between* (2010), *East ~ West epistemological convergence* (2016), *people in diaspora* (2018), and *diaspora curriculum theorizing* (2021).

Exile pedagogy and curriculum hold three qualities of in-betweenness: the epistemology of in-betweenness, the courageous aspect of teaching in-between, and the contested nature of teaching in-between. The epistemology of in-betweenness are illustrated in a wide array of literature such as philosophers in exile (e.g., Grathoff, 1989); women in exile (e.g., Afkhami, 1955/1983); writers in exile (e.g., Robinson, 1994); art of memory in exile (e.g., Píchová, 2002); exilic and diasporic filmmaking (e.g., Naficy, 2001); film, media, and the politics of place (e.g., Naficy, 1999); the making of exile cultures (e.g., Naficy, 1993); exiles and communities (e.g., Pagano, 1990); postmodern discourses of displacement (e.g., Kaplan, 1996); exiles, diasporas, and strangers in art (e.g., Mercer, 2008); reluctant exiles (e.g., Skelton, 1994); feminism, diasporas, and neoliberalisms (e.g., Grewal, 2005); dialectics of exile (e.g., McClennen, 2004); and contested landscapes: movement, exile, and place (Bender and Winer, 2001). There is more a sense of blurredness, intersectionality, or multiplicity and a sense of being in the midst in approaches to exile in arts, films, media, fictions, and poems. This discursive, multifaceted, complicated, sometimes contested nature of exile is in line with an evolving in-betweenness of exile pedagogy and curriculum.

The courageous aspect of teaching in-between is particularly influenced by radical democratic orientations illuminated through Freire's *pedagogy of the oppressed* (1970/1992), education for critical consciousness (1997), and *teachers as cultural workers* (1998);

Freire & Faundez's *learning to question/pedagogy of liberation* (1989); Palmer's (1998) *courage to teach*; public pedagogy of Sandlin et al. (2010); Schultz's *spectacular things happen along the way* (2008/2018), *listening to and learning from students* (2011), and *teaching in the cracks* (2017); Giroux *teachers as intellectuals* (1988) and *critical public pedagogy* (2004); Kincheloe's (2008) *critical pedagogy*; Asante's (2017) *revolutionary pedagogy: A primer for teachers of Black children*; King's (2015) *Dysconscious racism, Afrocentric praxis and education for human freedom*; McLaren's (2002) *critical pedagogy*; Grande's (2004/2015) *Red pedagogy*; Lather's (1991, 1998) *feminist pedagogy*; Kozol's *savage inequalities* (1991) and *letters to a young teacher* (2008); Crocco et al. (1999) *pedagogies of resistance*; Simon's (1991) *teaching against the grain*; Cochran-Smith's (1991, 2001, 2004) *learning to teach against the grain and teach for social change*; teaching for social justice of Ayers, Hunt, and Quinn (1998); *learning to teach for social justice* of Darling-Hammond, French and Garcia (2002); bell hooks' *teaching to transgress* (1994), *teaching community* (2003), and *teaching critical thinking* (2010), Said's *intellectuals as exiles* (1994), Ayer's (2004, 2006) *teaching toward freedom*, and *teaching the taboo* of Ayers and Ayers (2011).

The radical democratic quality of teaching creates an in-between space for educational workers to *exile voluntarily to teach in-between* (He, 2010). This aspect of exile in-between is illuminated in an oral tradition of Confucianism: A good teacher should be able to remove himself/herself from the crazy materialistic world, seek a balanced human condition in-between unbalanced and contested contradictions and complexities within nature and humanity, and develop a clear vision to *cultivate beauty, integrity, justice, and humanity* (also see Schubert, 2009a). Many educational workers who choose to teach in-between not only question [what] is worthwhile [to teach], for whom it is worthwhile [to teach], and how we make [teaching] worthwhile (Schubert, 2009b, p. 136), but also confront issues of equity, equality, social justice, societal change, and democratic human conditions through pedagogical theory and praxis.

The contested nature of teaching in-between draws substantially on the works of race, gender, class, and power of Black feminist thought/Black womanism (e.g., Baszile, 2015; Baszile et al., 2016; Davis, 1983; Guy-Sheftall, 1995; Collins, 1991/2000; hooks, 1999; James and Sharpley-Whiting, 2000/2001; McClaurin, 2001; Morrison, 1992, 2008; Phillips, 2006; Ross, 2015; Smith, 1983/2000; Walker, 1967/1983, 1997); Chicana feminist thought (e.g., Anzaldúa and Keating, 2002; Arredondo et al., 2003; García, 1997); critical race feminism (e.g., Wing, 2000, 2003); third world feminism (e.g., Mohanty, 2003/2005; Narayan, 1997); post/neocolonial feminism/ecofeminism (e.g., Anzaldúa, 1987, 1990; Mies and Shiva, 1993; Minh-ha, 1989; Mohanty, 2003/2005); Native American social and political thought (e.g., Grande, 2004/2015; Lomawaima, 1994; McCarty, 2002; Ng-A-Fook, 2007); indigenous ways of being, knowing, and doing (e.g., Archibald, 2008; Archibald et al., 2019; Tuhiwai Smith, 1999/2012; Tuhiwai Smith et al., 2018; Wilson, 2008; also Denzin et al., 2008); postmodern geography (e.g., Soja, 1989); the third space (Soja, 1996/2000; Wang, 2004, 2006, 2010); critical geography (e.g., Harvey, 2001); social and cultural geography (Del Casino and Vincent, 2009; Anderson et al., 2003); and spatial justice (Soja, 2010). While the intersectionality of race, gender, class, and power is always central to Black feminist thought/Black womanism, the intersectionality of repatriarchal historical analysis, spirituality, migration, displacement, slavery, racism, sexism, classism, imperialism, colonialism, heterosexism, ageism, ableism, anthropocentrism (i.e., human supremacism), speciesism, and other forms of oppression is illuminated in Chicana feminist thought, critical race feminism, third world feminism, and post/neocolonial feminism/ecofeminism. Indigenous ways of being, knowing, and doing connect critical theory with indigenous knowledge and socio-political contexts of indigenous education to develop transcendent theories of decolonization and advocate the liberty of indigenous language and cultural rights and intellectualism. Postmodern geographers, critical geographers, social and cultural geographers engage in this complex intersectionality within vibrant special dynamics of socio-political, cultural, and linguistic contradictions, complexities, and possibilities.

With three qualities distinguished from other forms of pedagogy and curriculum: the epistemology of in-betweenness, courageous aspect of teaching in-between, and the contested nature of teaching in-between, exile pedagogy and curriculum inspire us to teach to tensions, contradictions, and complexities in-between contested race, gender, class, and power with equity, equality, social justice, and human freedom as explicit goals. The power of exile pedagogy and curriculum lie in educational workers' strong advocacy on behalf of individuals, groups, families, tribes, communities, and societies that are often at controversy, underrepresented, misrepresented, or excluded in official narratives. Exile pedagogy and curriculum connect the personal with the political and the practical with the theoretical through passionate participation in and critical reflection on teaching, learning, inquiry, and life with an "epistemological curiosity" (Freire and Macedo, 1995, p. 382) and with passion particularly in hard times. Exile pedagogy and curriculum encourage us to teach courageously in-between contradictions; move beyond boundaries; transgress orthodoxies; question mandates and regulations; educate rather than profit (Nussbaum, 2010); and "build on long-term, heart-felt engagement and shared efforts driven by commitment to equity, equality, social justice, freedom, and human possibility" (He, 2010, p. 471). Exile pedagogy and curriculum create a culture of resistance and builds a participatory movement to promote a more balanced and equitable human condition through personal and political acts of teaching in an increasingly diversified and contested world.

Diaspora curriculum theorizing

Most recently, I venture into diaspora curriculum theorizing. Diaspora curriculum draws upon a wide array of theoretical traditions such as conceptions of diasporas (e.g., Bruneau, 2010; Safran, 1991; Tölölyan, 1991); the breadth, diversity, and complexity of diasporas (e.g., Bhabha, 1990, 1994; Clifford, 1994, 1997; Hall, 1999, 2017a,b, 2019); diaspora consciousness, diasporic space, and the in-betweenness of diasporas (e.g., Aoki, 2005a,b; Bakhtin, 1981; Bhabha, 1994, 1996/2008; Clifford, 1994, 1997; Deleuze and Guattari, 1972, 1980, 1991; He, 2003, 2006, 2010, 2016, 2018; Said, 1994, 2000, 2002); decolonizing diasporas (e.g., Dei,

2017; Dei and Lordan, 2016; Figueroa-Vásquez, 2020; Haig-Brown, 2009, 2012; Tuck and Yang, 2012); diasporic imaginaries and diasporic futurism (e.g., Antonsich, 2010; Axel, 2002; Mishra, 1996; Steger, 2008), Afrofuturism (e.g., Anderson and Jones, 2016; Dery, 1994; Gipson, 2019; Jackson and Moody-Freeman, 2011; Womack, 2013), and Indigenous futurism (e.g., Dillon, 2012; Lempert, 2014, 2018; also Alfred, 1999; Ortiz, 2009).

Diaspora curriculum draws upon a wide array of conceptions of diaspora (e.g., Bruneau, 2010; Safran, 1991; Tölölyan, 1991). Diaspora (in Greek, διασπορά—“a scattering [of seeds]”) refers to the movement of a population sharing common ethnic identity who are either forced to leave or voluntarily leave their indigenous or ancestral lands and become residents in areas often far removed from their former homes (He, 2010, 2018). In a broader sense, diaspora refers to situations when indigenous peoples, immigrants, and emigrants are forced to leave or voluntarily leave their tribes, native lands, territories, communities, or countries due to such reasons as imperialism, colonialism, political persecution, economic exploitation, trade or labor migrations. While people in diaspora might not maintain strong ties with their homelands or native lands, they lack full integration into the host lands. This mobile and unsettling existence of diasporas complicates and creates *multiple senses of belonging* (Bader and Schieren, 2019). Diaspora is dedicated to the multidisciplinary study of the history, culture, social structure, politics and economics of both the traditional diasporas—Armenian, Greek, and Jewish—and those transnational dispersions which in the past three decades have chosen to identify themselves as “diasporas.” These encompass groups ranging from the African-American to the Ukrainian-Canadian, from the Caribbean-British to the new East and South Asian diasporas.

While engendered by the mobile, unsettling, interdisciplinary, and transnational existence of diasporas, diaspora curriculum also draws upon the breadth, diversity, and complexity of diasporas. A group of anthropologists or cultural theorists (e.g., Bauböck and Faist, 2010; Bhabha, 1990, 1994, 1996/2008; Clifford, 1994, 1997; Hall, 1999, 2017a,b, 2019) broadened, diversified, and complicated the conceptions of diasporas. Drawing from Derrida’s (1982) notion of *différance* and Caribbean cultural diasporic aesthetics, Stuart Hall (1999) elaborated the unsettledness and unresolvableness of diasporas. For Hall (1999), the conception of diasporas cannot rest on “a binary conception of difference” (p. 7). Diaspora is “positional and relational, always on the slide along a spectrum without end or beginning” (p. 7). The reconfiguration of diasporas cannot be represented as “going back to where we were before ... there is always something else between” (p. 8). Diasporas “are dispersed forever from their homelands, to which they cannot literally return. Diasporas belong to “imagined communities to which there can be no return” (p. 172). They “must learn to inhabit more than one identity, dwell in more than one culture, and speak more than one language ... to speak in the unsettling place in-between languages means to constantly negotiate and translate across their differences” (p. 173). Such a diasporic experience invents “home from home” (Hall, 2017a,b, p. 172), a diasporic consciousness, a diasporic perspective, and a diasporic narrative to capture “the full complexities” and the displacements of “a collective predicament” (p. 171).

Paul Gilroy (1993) questioned “ethnic absolutism in cultural criticism” (p. 3) regarding the Black Atlantic diaspora. Gilroy perceived the Black Atlantic diaspora as “a counterculture of modernity” (pp. 1–40), a culture as “a non-traditional tradition, an irreducibly modern, exocentric, unstable, and asymmetrical cultural ensemble that cannot be apprehended through the Manichean logic of binary coding” (p. 198). This counterculture “is not specifically African, American, Caribbean, or British, but all of these at once, a Black Atlantic culture whose themes and techniques transcend ethnicity and nationality to produce something new” (Lott, 1993, cover). He also explores the Black Atlantic diaspora as it is manifested in black writing from the “double consciousness” of W. E. B. Du Bois to the “double vision” of Richard Wright to the compelling voice of Toni Morrison. By articulating the temporality, historicity, memory, and narrativity of the Black Atlantic countercultures, Gilroy (1993) reminds us “the long history of slavery, the legacy of scientific racism, and the complicity of rationality and terror in distinctively modern forms of domination” and “a long struggle for political and social emancipation, and critical visions of equality and difference” (Clifford, 1994, p. 317) that have been generated in the Black Atlantic diaspora. Drawing from Jacques Derrida’s notion of *différance* and cultural diasporic aesthetics, Homi Bhabha, James Clifford, and Stuart Hall broadened the conceptions of diasporas and complicates multiple senses of belonging for people in diaspora, which encapsulates the similar mobile, unsettling, interdisciplinary, and transnational nature of cross-cultural narrative inquiry. This diaspora curriculum theorizing is deeply embedded in my life experience as a Chinese woman scholar and a curriculum worker wondering amongst constantly changing and complicating Eastern and Western theoretical traditions, histories, languages, cultures, and geographical locations.

Diaspora curriculum is illuminated by the breadth, diversity, and complexity of diasporas through diaspora consciousness and diasporic space in the works of James Clifford (1994, 1997) on *diaspora consciousness and diasporic space*, Homi Bhabha on *location of culture* (1994) and *culture’s in-between* (1996/2008), Gilles Deleuze and Félix Guattari (1972, 1980, 1991) on *rhizome, interbeing, intermezzo, multiplicity, and line of flight*, M. M. Bakhtin (1981) on *double-voiced, double accented, and double language hybrid*, and Ted Aoki (2005a, b) on *teaching as indwelling between curriculum worlds* (He, 2021, 2022).

To theorize diasporas (Brazier and Mannur, 2003) begins with decolonizing diasporas. To decolonize diasporas, we need to “involve repatriation of Indigenous land and abolition of slavery” (Tuck, 2015, p. 444). Too often “diaspora theory ignores the presence of Indigenous peoples who were already in place when the first and the last diasporic peoples were forced or chose to come to a land” (Haig-Brown, 2009, p. 16). For Haig-Brown (2009), “to ignore the trauma of those people who have been displaced here to make room, first for the colonizers and then for those who came after under all sorts of the other conditions—from slavery to starvation to war to straightforward immigration for the promise [of] a new world—is to perpetuate ... epistemic violence” (p. 16). Haig-Brown (2009) called the diaspora theorists to “take seriously not only the land from which one comes, but the land and original people of the place where one arrives” (p. 16).

To decolonize diasporas, we need to “unsettle and dismantle the logics of colonial modernity/coloniality” and recognize the resistance of peoples of African descent as Afro-diasporic imaginaries—Afro-futurities—that “subvert and resist modernity and

coloniality” and offer new ways to approach questions of home, location, belonging, difference, and justice (Figueroa-Vásquez, 2020, p. 16). Decolonizing diasporas helps create a critical space to “examine how themes of intimacy, witnessing, dispossession, reparations, and futurities are remapped ... by tracing interlocking structures of oppression, including public and intimate forms of domination, sexual and structural violence, sociopolitical and racial exclusion, and the haunting remnants of colonial intervention” (Figueroa-Vásquez, 2020, pp. 1–2). Further, understanding of theories of decolonization and anti-colonialism is “a continuous process of challenging colonial and neo-colonial legacies, relations and power dynamics, taking up the subject of anti-colonial praxis and its specific implications—the larger questions of schooling and education in global and, particularly, diasporic contexts” (Dei and Lordan, 2016, p. vii). The *cartographies* (brah, 1996) of decolonizing diaspora can be also traced to a wide array of works on decolonization such as Karen R. Lawrence (1992) on *decolonizing tradition*, Linda Tuhiwai Smith (1999/2012) on *decolonizing methodologies*, Jo-ann Archibald (2008) on *Indigenous storywork: educating the heart, mind, body, and spirit*, Kuan-Hsing Chen (2010) on *Asia as method*, Angel Lin and Peter Martin (2005) on *decolonization and globalization*, Kagendo Mutua and Beth Blue Swadener (2004) on *decolonizing research in cross-cultural contexts*, Leigh Patel (2016) on *decolonizing educational research*, Bagele Chilisa (2012) on *Indigenous research methodologies*, Margaret Kovach (2009/2012) on *Indigenous methodologies*, and Chela Sandoval (2000) on *methodology of the oppressed*.

In addition to its breadth, diversity, and complexity, another illuminating aspect of diaspora curriculum is the evolving diasporic imaginaries (e.g., Axel, 2002). Instead of dwelling on the traditional notion of diaspora as a spatial separation between homeland and host country, the “diasporic imaginary” is a space of imagination which “account[s] for the creation of the diaspora ... through formations of temporality, affect, and corporeality” (Axel, 2002, p. 412). The “diasporic imaginary” reinterprets the imaginary as the creation of a shared diasporic space of dreams, imaginations, and visions to cultivate diasporic communities—“imagined communities” (Anderson, 1991). The “diasporic imaginary” (Mishra, 1991, 2007) is interconnected with “global imaginary” (Steger, 2008) as a consciousness of belonging to a global community of shared ideas and interests. Diasporic imaginaries represent a multiplicity of temporalities, localities, traditions, identities, and subjectivities engendered by shared diasporic experiences, multiple senses of belonging, and multiple processes of becoming.

Afrofuturism (Dery, 1994; Nelson, 2002) and Indigenous futurism help decolonize diasporic imaginaries to center shared diasporic experiences of dispossession, deprivation, oppression, exploitation, violence, exclusion, persecution, and invasion. Afrofuturism is a cultural aesthetic, philosophy of science and philosophy of history that explores the developing intersection of African diaspora culture with technology. Afrofuturism addresses themes and concerns of the African diaspora through technoculture and science fiction, encompassing a range of media and artists with a shared interest in envisioning Black futures that stem from Afrodiasporic experiences. An Afroturistic concept, *Astro-Blackness*, “represents the emergence of a black identity framework within global technocultural assemblages, migration, human reproduction, algorithms, digital networks, software platforms, bio-technical augmentation ... [where] racialized identities are increasingly materialized ... humans and techniques have co-evolved together” (Anderson and Jones, 2016). Afrofuturism is “an intersection of imagination, technology, the future and liberation” (Womack, 2013). Afrofuturism is the philosophy of science fiction, and history that traverses across African Diaspora cultures with technology to explore the African American experience, specifically slavery. Afrofuturism is “a way of imagining possible futures through a black cultural lens ... [It is] a way to encourage experimentation, reimagine identities, and active liberation” (LaFleur, 2011).

Indigenous Futurism (Dillon, 2012) is a movement consisting of art, literature, comics, games, and other forms of media which express Indigenous perspectives of the future, past, and present in the context of science fiction and related sub-genres. Such perspectives may reflect Indigenous ways of knowing, traditional stories, historical or contemporary politics, and cultural realities. Like Afrofuturism, Indigenous Futurism encapsulates multiple modes of art-making from literature to visual arts, fashion and music, processes of decolonization (Dillon, 2012). Using tools like slipstream, worldbuilding, science fiction and anthropological First Contact scenarios, Indigenous communities construct self-determined representations and alternative narratives about their identities and futures. Indigenous Futurists critique the exclusion of Indigenous peoples from the contemporary world and challenge notions of what constitutes advanced technology. Indigenous Futurists question the digital divide and recognize that Indigenous peoples have been purposefully excluded in history from accessing media technologies and exist outside of modernity. The widespread use of personal computers and the Internet following the Digital Revolution created conditions in which, to some extent, Indigenous peoples may participate in the creation of a network of self-representations.

Inspired by diasporic imaginaries, particularly Afrofuturism and Indigenous Futurism, diasporic futurism is a multicultural, multilingual, and multiracial aesthetic, philosophy of science and philosophy of history that explores the developing intersection of language, culture, identity, race, gender, class, power, and place in diaspora with technology. Diasporic futurism addresses themes and concerns of the multicultural, multilingual, and multiracial aesthetic diaspora through technoculture and science fiction, encompassing a range of media and artists with shared interests in envisioning alternative futures that stem from diasporic experiences. Such alternative futures shatter white supremacy, racism, xenophobia, misogyny, homophobia, transphobia, islamophobia and settler colonialism that perpetuating an emboldened hatred of the difference of minoritized communities.

Cross-cultural narrative imagination in hard times

In addition to its breadth, diversity, and complexity, another illuminating aspect of cross-cultural narrative inquiry is the evolving cross-cultural imaginaries, where we can keep our hopes and dreams alive in hard times when white supremacy, anti-Black/anti-Indigenous/anti-Asian racism, xenophobia, misogyny, homophobia, transphobia, Islamophobia, and settler colonialism are

perpetuated by hatred of differences (He et al., 2021). Such cross-cultural imaginaries invent cross-cultural futurities and cultivate radical possibilities (Anderson and Jones, 2016; Anyon, 2005; Womack, 2013) and radical imagination (Freire, 2007; Giroux, 2007; Greene, 1995; Jackson and Moody-Freeman, 2011; Kelley, 2002; Lake, 2013; Mills, 1959/2000; Olson and Worsham, 2007). Such cross-cultural futurities exhilarate cross-cultural consciousness that educates hope (Harvey, 2000), evokes “different histories and different futures” (Giroux, 2017, p. xiii), and cultivates radical love so that we “could find the strength, faith, and humility to establish solidarity and struggle together to transform the oppressive ideologies and practices” (Darder, 2017, p. 80) to build solidarity across differences to fight against myriad forms of oppression. Such cross-cultural futurities inspire “optimism over despair” (Chomsky, 2017), love over hatred, and possibilities over impossibilities (Ayers, 2016; hooks, 2000; Darder, 2017).

Such cross-cultural imaginaries inspire us to invent creative strategies to teach, research, and live toward freedom and social justice in troubling times. Such cross-cultural imaginaries continuously encourage us to cultivate “solidarity, integrity, and humility” (Stovall, 2016, p. 54) to counter authoritarian and dominant narratives and transgress orthodoxies and bureaucratic procedures (e.g., Archibald, 2008; Archibald et al., 2019; Chilisa, 2012; hooks, 1994; Love, 2019; Maparyan, 2012; Patel, 2016; Phillips, 2006; Sandoval, 2000; Tuck, 2015; Tuck and Yang, 2012; Tuhiwai Smith, 1999/2012; Tuhiwai Smith et al., 2018; Walker, 1997; Wilson, 2008). Such cross-cultural imaginaries enable us to build up courage to *voluntarily exile* (He, 2010) from *commodified* (Illich, 1970), *acquisitive* (Dewey, 1933; Schubert, 2009a), and *deskilling* societies (Apple, 1982, 1986, 2001) to *make the impossible possible* (Ayers, 2016), to keep the boundless human potential evolving (Nussbaum, 1997; Schubert, 2009b; Siddle-Walker, 1996), to create “more equitable and just public spheres within and outside of educational institutions” (Mohanty, 1989, p. 207), to build better human conditions in-between contradictions and complexities, and to passionately participate in the life of schools, families, communities, places, and spaces. Such cross-cultural futurities invigorate cross-cultural space for “imagined communities” (Bhabha, 1994, p. 5) where cross-cultural workers work with other educational workers such as researchers, educators, teachers, administrators, parents, students, community workers, and policy makers to heal the humanity and planet with “shared principles and visions” for “desirable collective futures” in “a world of increasing complexity, uncertainty, and fragility” (UNESCO, 2020, pp. 2–5) and to build diverse, resilient, healthy, peaceful, and “thriving sustainable futures” (UNESCO, 2022a,b, p. 5) for all.

Introduction

The United Nations (UN) initiatives on sustainable development have gained momentum in a world distinguished by climate crisis, ecological crisis, and global injustices. In the following, these initiatives are addressed with particular attention to the impact on curriculum. The scope is theoretical, identifying and discussing some vital issues for curriculum theory, that should be considered. I first give a short presentation of UN's Agenda 2030, including the 17 Sustainable Development Goals, followed by reflections on the key concepts of curriculum and democracy. A major contradiction within the history of the UN sustainable development initiatives is pointed out that consists of promises that persistently have been followed by the lack of sufficient action, also reflected in the so-called democratic impasse of sustainable development. Critical curriculum studies are called for, exploring both hegemonic imaginaries involved and the significance of context. A multi-level approach to curriculum processes is suggested and exemplified by an account that combines Basil Bernstein's conception of recontextualization with Seyla Benhabib's critical cosmopolitanism, conceiving the recontextualizations of universal norms as democratic iterations.

Finally, the conception of the common good is considered as a critical premise within a curriculum theory oriented toward studies of the UN's Agenda 2030 and the Sustainable Development Goals. Decisive is here the suggestion that the common good, in the SDGs addressed on a general level, also involves recontextualizations expressed in particular curriculum practices, on which hegemonic imaginaries continuously have an impact.

Agenda 2030 and the UN's sustainable development goals

On September 25, 2015, the United Nations General Assembly, through the Resolution 70/1 *Transforming our World: the 2030 Agenda for Sustainable Development* (United Nations, 2015), adopted the 17 Sustainable Development Goals (SDGs). The notion of SDGs, also referred to as the "Global Goals" (French and Kotzé, 2018), was first proposed at the 2012 UN Conference on Sustainable Development (the "Rio +20 Summit"), to replace the Millennium Development Goals (MDGs) which were launched in 2001 and expired in 2015. Through intergovernmental negotiations and open-ended dialogs with civil society including various groups, the draft featuring 17 goals and encompassing 169 targets and subsequent indicators was presented. Unlike the MDGs that were particularly oriented toward developing countries, the SDGs are universally applicable, including all nations globally.

The goals are framed by the concept of *sustainable development*, which, within United Nations, has a history going back to the 1980s and was famously introduced as a key concept by the World Commission on Environment and Development (appointed by United Nations General Assembly in 1983) in the report *Our Common Future* in 1987. The report states that sustainable development "meets the needs of the present without compromising the ability of future generations to meet their own needs" (World Commission on Environment and Development, 1987). With the concept of sustainable development, the United Nations brought together a long-term engagement strategy for social development and elimination of poverty with the acknowledgment of ecological crisis, including human-induced climate change. In a global call to action the commission states:

The issues we have raised in this report are inevitably of far reaching [sic] importance to the quality of life on earth—indeed to life itself. We have tried to show how human survival and well-being could depend on success in elevating sustainable development to a global ethic. In doing so, we have called for such major efforts as greater willingness and cooperation to combat international poverty, to maintain peace and enhance security world-wide, and to manage the global commons.

World Commission on Environment and Development (1987).

In 1992, *Our Common Future* was followed by the United Nations Conference on Environment and Development in Rio de Janeiro. From here emerged the UN conventions on biodiversity (United Nations, 1992a), climate change (United Nations, 1992b), desertification (United Nations, 1992c), the Rio Declaration (United Nations, 1992d), and Agenda 21 (United Nations, 1992e), a global action plan for the 21st century. With Agenda 2030 and the SDGs, adopted by UN General Assembly more than twenty years later (United Nations, 2015), sustainable development has now been granted an unprecedented status and role as the decisive strategy to guide future strategies and actions. While the 17 Sustainable Development Goals definitely constitute the backbone of Agenda 2030, other elements are included as well that concern financing, partnerships, technology facilitation, monitoring, reporting, and evaluation.

In Rio in 1992, education was already explicitly addressed in Chapter 36 of Agenda 21. Here, it is stated that education is “linked to virtually all areas in Agenda 21” (United Nations, 1992e). Chapter 36 even addresses public awareness and training and calls for the reorienting of education toward sustainable development. UNESCO was appointed as responsible for this educational engagement and monitored the UN Decade of Education for Sustainable Development (ESD) (2005–2014) as a major achievement. The significance and integration of education is restated in Agenda 2030 with quality education addressed as SDG 4, both conceived of as an aim in itself, and a means to promote other aims.

Promises and insufficient action

The UN resolution *Transforming our World: the 2030 Agenda for Sustainable Development* (United Nations, 2015) concludes that significant progress has been made in meeting several of the development challenges continuously addressed by the United Nations. Hundreds of millions of people have emerged from extreme poverty, global access to education has increased, and information and communication technology has been spread. However, the resolution makes equally clear that major threats to life are extended, and in vital areas, the situation has deteriorated distinguishably due to rising social and economic inequalities within and between countries, natural resource depletion and environmental degradation, climate change, putting the survival of societies and the biological support systems of the planet at risk.

More severe and disturbing when it comes to the history of this initiative, is the fact that in the early 1990s, social inequalities, climate change, and ecological crisis were addressed as pivotal, urgent concerns in United Nations conventions and declarations and subsequent calls for action. Almost 40 years later, the calls for action are even more urgent, particularly with regard to the ecological and climate crisis. The contradiction between promises and insufficient action appears to be a main flaw in the history of the policy of sustainable development, jeopardizing the legitimacy of the initiative itself. As far as education is a part of this story, the stated contradiction also has bearings on the global education policy of education for sustainable development.

Curriculum and the nation-state

Curriculum as a key concept in this entry is an elusive concept, partly due to the broadness of the curriculum field that encompasses student experiences on learning, teacher practices, written documents, and even ideological imaginaries with bearings on education. Moreover, within the context of an international encyclopedia, it is not without problems to refer to a concept emerging from Anglo-American traditions with an emphasis on curriculum-making in local contexts, reflecting school systems that differ considerably from structures and practices in other countries. Thoroughly documented and well explored are, for instance, similarities and differences between this curriculum tradition and the North European didactic tradition in which teachers have been licensed to interpret an open national curriculum while fulfilling the societal mandate of *Bildung* (“formation”; “edification”) (Hopmann and Riquarts, 2000; Künzli, 2000; Westbury, 2000).

“Curriculum is the heart of education,” Null (2011, p. 1) concludes, pointing at how curriculum expresses what should be taught, combining thought, action, and purpose. The emphasis on subject matter as a defining aspect of curriculum is summed up in the question coined by Spencer (1861): What knowledge is of most worth? Michael Apple, drawing attention to political and ideological aspects, rephrases the question as: Whose knowledge is of most worth? (Apple, 2004, p. xix). In the renewal of the German didactic tradition, in the 1980s, Wolfgang Klafki placed current, societal key challenges in the crucial content position of the didactic triangle (the other two apexes constituted by the students and the teacher), including concerns for environment, peace, and global justice (account in English, see Klafki, 1998).

Klafki exemplifies how global issues have been introduced to curriculum theory, challenging the impression of the general national framing of curriculum within the Westphalian order (see Kvamme, 2021). Since Klafki's works in the 1980s, these challenges have been elaborated within various forms of cosmopolitanism, including the critical cosmopolitanism of Benhabib (2006, 2011), considered in *Recontextualizations, hegemony, and democratic iterations* section below. The role of the nation-state also emerges as a decisive aspect when we now turn to democracy as another key concept in this entry.

The democratic impasse

Within the studies of governance, the contradiction stated above between universal claims adopted unanimously by the nations of the world and the lack of corresponding action have been discussed with regard to the Western, liberal democracies. William Lafferty

employs Carl Cohen's definition of democracy as "that system of community government in which, by and large, the members of a community participate, directly or indirectly, in the making of decisions which affect them all" (Lafferty, 2012, p. 299). Lafferty demonstrates how the notion of community in Western societies historically has been defined by geographical boundaries. Significant here is the development of nation-states, corresponding with a notion of citizenship based on individual membership from which representations of interest emerge. In contrast, sustainable development involves a notion of community based on ecological interdependence with an expanded notion of citizenship that incorporates the interests of future generations, the world's poor, and possibly the interests of other species (Lafferty, 2012, p. 305).

To Lafferty, the contradiction between the notions of community and citizenship demonstrates a main challenge involved in the United Nations' sustainable development agenda. Virtually all nations of the world have formally subscribed to the goal of sustainable development, and the goal is to be realized through democratic means, but the existing democratic structures privilege the interests of the demarcated jurisdictions of nation-states and do not accommodate the normative notions expressed in the goal. Lafferty's conclusion is expressed as "the impasse of dysfunctional democracy," cf. the subtitle of the paper referred to here (Lafferty, 2012).

The tensions between existing liberal democracies and implications of sustainable development are also addressed by Westall (2015). In addition to the restrictions constituted by defined political geographies and legally defined citizens, she points out how liberal democracies have given economic growth primacy while not taking environmental limits into account, often guided by short-termism that makes individual freedom a dominant ethic. In contrast, sustainable development implies considerations on long-term impacts on all affected people including intragenerational and intergenerational equity, an integration of economic, environmental and social considerations accentuating environmental limits to human activity, and an emphasis on shared goals and shared values (including future orientation and concern for nature).

Both Lafferty and Westall nevertheless accentuate democracy as the preferred model of governance facing the transformation to sustainable development with particular reference to participation and inclusion. This democratic framing is significant in the context of Agenda 2030. The general commitments in the crucial Goal 16 are to "promote just, peaceful, and inclusive societies", but democracy is not explicitly mentioned in the SDGs, according to Langford (2016, p. 173), ensured by China in the drafting process. Here, following Lafferty and Westall, I interpret Goal 16 within the context of a deliberative conception of democracy. As a consequence, Lafferty's formulation of the impasse of democracy should be taken into account.

Curriculum and the SDGs

As stated above, the United Nations' engagement with sustainable development has prompted the global education policy of Education for Sustainable Development (ESD) initiated and followed up on by UNESCO. Currently within Agenda 2030, this engagement is expressed in the *Framework for the implementation of ESD beyond 2019 "ESD for 2030" (2020–2030)* (UNESCO, 2019) and *Education for Sustainable Development A roadmap. ESD for 2030* (UNESCO, 2020). Both of these documents are quite general in their approach. The vision is "to build a more just and sustainable world through strengthening ESD and contributing to the achievement of all 17 Sustainable Development Goals" (UNESCO, 2020). The scope encompasses both formal and informal learning arenas. One of five priority action areas is to advance education policies, "including those that concern learning environments, curricula, teacher education as well as student assessment" (UNESCO, 2019, p. 26). Here, curriculum is quite narrowly conceived and clearly distinguished from education policy. A similar conception is reflected in the global indicator to target 4.7.1 referring to the extent "(i) global citizenship education and (ii) education for sustainable development are mainstreamed in (a) national education policies; (b) curricula; (c) teacher education; and (d) student assessment" (UNESCO, 2019, p. 51).

The framing accentuates a strategy in which UNESCO promotes curriculum development on a national level as a contribution to build a more just and sustainable world. The indicators are integrated in a monitoring process where nation states report back to UNESCO. As we see, curriculum is here positioned within the context of nation-states. The aim is definitely not to establish a global curriculum but to encourage nation-states to develop curricula that accommodate the global goals expressed in Agenda 2030.

This structure prompts more general considerations on the relationship between global education policy and curriculum. As stated above, UNESCO's strategy of education for sustainable development is an instance of global education policy as an aspect of institutional globalization (Langford, 2016). Rizvi and Lingard (2010) point out how global education policy is framed "by discourses which, while they often have their gestation in various global networks, are negotiated and rearticulated at regional, national, provincial and local levels" (p. 44). Consequently, it is decisive to recognize "the simultaneous plays of the local, national and global as spatial relations in the education policy cycle" (Rizvi and Lingard, 2010, p. 15; see also Kvamme, 2020a). The term "policy cycle", coined by Ball (1994), refers to the interactive set of relationships between various contexts. It rejects a one-way, linear account of relationships between the setting of policy agendas.

From this multilayered approach, the traditional divide between education policy studies and curriculum studies is not sufficient (Rizvi and Lingard, 2010, pp. 93–94). Rizvi and Lingard's suggestion is to include curriculum studies within the field of policy studies. As important as this might be, from the perspective of curriculum studies, one should as well consider the impact of education policy on curriculum.

Of particular relevance for the UNESCO follow-up on Agenda 2030 is the persistent discussion within curriculum studies of the relationship between theory and practice. In a classical take on this matter, Goodson (1994) points out the prescriptive tendencies in curriculum theories, whether the orientation is guided by scientific management and analysis or by the critique of such an

approach guided by meliorism or impossibilism. In either case, the approaches ignore “what is in pursuit of what *might be*” (Goodson, 1994, p. 29). In other words, Goodson calls for a curriculum theory that is sensitive to particular contexts.

With regard to curriculum studies involving the SDGs, a proposal here would first of all be to adopt a multilevel approach including the global, national, and local levels and second, ascertain that the mediations between education policy and curriculum making are accommodated in such a design. A third concern would be to avoid a one-sided emphasis on a top-down perspective and be aware of bottom-up processes as Rizvi and Lingard (2010) express in the concept of policy circle quoted above. Following Goodson (1994), the context of educational practices is particularly significant here.

Recontextualizations, hegemony, and democratic iterations

A multi-level perspective raises the problem of how movements and uptakes of values, imaginaries, ideas between the various levels are to be understood. Here various approaches have been established (see for instance Røvik's (2016) study of knowledge transfer as processes of translation). Addressing the democratic impasse considered above, the concept of recontextualization as formulated by Bernstein (2000) seems to offer a productive entrance. Bernstein draws attention to how discourses are *pedagogized* when recontextualized into educational contexts. A transformation is involved because “there is a space in which ideology can play” (Bernstein, 2000, p. 32). Within Bernstein's theory, recontextualizations concern how social discourse becomes part of legitimate educational knowledge (Loughland and Sriprakash, 2016). UN Agenda 2030 is fraught with normativity and values, and the research literature demonstrates that hegemonic structures seem to be involved in the recontextualization processes.

With regard to the ESD history, a few examples may suffice to demonstrate how the recontextualization processes involves ideology, here conceived of as the maintenance of current power relations (Ricoeur, 2008). Sauvé et al. (2005) note how the ESD agenda has prioritized economic development at the expense of environmental concerns. Furthermore, studies of the UN Decade of Education for Sustainable Development suggest that the ESD agenda has been increasingly adaptable to neoliberalism, reducing political issues to questions of individual preferences and behavior (Huckle and Wals, 2015). Others demonstrate how ESD has eased the socially conflicting nature of the ecological crisis (Gonzales-Gaudiano, 2016).

The possible impact of hegemonic structures on ESD processes has also been problematized. Stefan Bengtsson (2016) refers to what he claims to be a paradox in much of the scholarly literature criticizing ESD. ESD policy supposedly exercises a power of influence while reproducing hegemonic discourse. Still, Bengtsson claims, there seems to be a space for critical reflection and even deviance. With reference to the political theory of Laclau and Mouffe (1985), Bengtsson calls for a logic of contingency to replace the logic of necessity that he holds distinguishes scholars who assert that the ESD agenda serves hegemonic forces. However, as one of these scholars expressed in a rejoinder to Bengtsson, the claim that hegemonic structures are at work does not imply that there is no space for dissensus (Jickling, 2016). In any case, Bengtsson's reminder demonstrates the significance of the productive work exercised on all levels in the education policy cycle.

The moral philosopher and political theorist Seyla Benhabib offers with her critical cosmopolitanism an approach that accommodates both universal claims and the significance of context in processes of recontextualization. With the concept of democratic iterations, Benhabib (2006, 2011) notes how human rights are subject to reinterpretations when articulated in new contexts and make space for plurality, disagreements, and conflict. In one regard, Benhabib claims that such iterations will take place in any recontextualizing process, confirming the significance of context in empirical studies. However, democratic iterations has a normative dimension, as well, drawing attention to processes that open up or restrict the space for democratic iterations, a dimension expressed in the concept of jurisgenerativity, employed by Benhabib (2011) with reference to Robert Cover.

From her position within critical theory (Benhabib, 1986), Benhabib has developed a political theory of deliberate democracy (Benhabib, 1996) that challenges the boundaries of the nation-state. Central is her conception of enlarged thought (Benhabib, 1992), drawn from Arendt (1978), that includes everyone who may possibly be influenced by the action in question in the act of deliberation.

Benhabib's conceptions are consistent with the perspectives within critical pedagogy as accounted for above. In my own empirical studies, I have employed Benhabib's approach in a multi-level exploration of recontextualizations of environmental ethical values expressed within the UN agenda in Norwegian educational contexts and even in the school strikes for the climate (Kvamme, 2018, 2019, 2020a,b; see also Wahlström, 2009 for the employment of Benhabib within curriculum studies). I suggest that hegemonic processes are at work, including anthropocentrism, neoliberalism, and the boundaries of the nation-state, but also identify how the environmental ethical values formulated by the United Nations become resources for critique, empowerment, and transformative action. These studies demonstrate the decisive normative dimension of the United Nations' sustainable development agenda. This aspect is what I will address in the following section focused on relations between curriculum, deliberation, and ethics.

Deliberation and the ethical dimension involved

Deliberative perspectives in modern curriculum theory are strongly connected to the American curriculum scholar Joseph Schwab and his conceptions of the practical (Schwab, 1969). Decisive is the priority given to deliberative practices concerning practical problems, initiating further discussion by other scholars. William A. Reid's considerations on the relationships between deliberation and ethics are particularly interesting with regard to issues raised in this entry. Reid (1994) proposes that curriculum problems are

uncertain, practical, and moral problems. The practical aspect is mainly due to the fact that curriculum problems demand solutions in the form of action, whether as written curriculums or in the actual teaching in the classroom. The ethical aspect is made visible in the formulation of the major question posed as “What *ought* we to do?” leading to further questions of responsibility. The ethical responsibility involves all who are affected by the action being chosen. The uncertainty is pointing at the particularity of curriculum work. It always occurs within a unique context. How are curriculum problems to be dealt with, then? In his proposal, Reid refers to deliberation, specifically “the notion of inquiry” through which practical problems have to be resolved involving all who are affected, influencing and determining moral, political, and social actions (Reid, 1994, p. 18).

Reid's perspective is specific and practical, reflecting school systems in which curriculum work traditionally has been carried out locally. Although definitely not multi-layered in orientation, his perspectives nevertheless contribute to the discussion carried out here. First of all, Reid notes the significance of context, as emphasized above with reference to Benhabib. Second, Reid premises that curriculum practices as deliberations involve all who are affected, and finally, they emerge as an ethical responsibility.

Reid's contributions exemplify how curriculum theory until recently has been almost solely framed within geographical boundaries determining notions of community and participation. The message from cosmopolitan theory is that the local context is never just local (Beck, 2006; Mannion, 2015; Benhabib, 2006, 2011; Papastephanou, 2012). In numerous ways, the global has impact on the local and expands those affected by the chosen action. The intimate relationship between community and curriculum exposed in Reid's account is radically enhanced when the SDGs and Agenda 2030 are taken into account. Here, the question posed by Reid of what ought we to do emerges as a political issue and a policy task that, following the policy definition of Rizvi and Lingard (2010, p. 7), is concerned with “the authoritative allocation of values.” The ideal of deliberation is retrieved in the drafting process that produced UN Agenda 2030 and the 17 SDGs. Fox and Stoett (2016) contrast this process with the elite donor-driven process that led to the Millennium Development Goals and conclude that the 2030 Agenda process facilitated several arenas for citizen participation, and opened new paths toward the establishment of global democratic governance.

The participatory process is a main reason for ending up with as many as 17 goals (Langford, 2016) that constitute a thematic repertoire ranging from poverty, health, education, and inequality to water, energy, work, infrastructure (including climate, life on earth and underwater), peace, security, and good governance.

However, Fox and Stoett (2016) conclude that, despite their positive assessment, the drafting process remained far from an ideal participatory democracy. Others have been even more critical, demonstrating how hegemonic forces of anthropocentrism and neoliberalism are expressed in the document adopted by the United Nations General Assembly (Adelman, 2018; Kotzé, 2018).

This discussion confirms the normative and ethical dimension involved, echoing Reid's insistence on an ethical responsibility in curriculum practices conceived of as deliberation. Without the ethical dimension, the call for sustainable development is not justified (Kemp, 2011; Lafferty, 2012). Decisive is the concern for intragenerational and intergenerational justice for all and the protection of life on earth in all its diversity. Although the SDGs should probably not be considered a global curriculum, it is conspicuous how Agenda 2030, at its most general level, is a call to transform people, practices, and structures everywhere. This ambition transcends educational institutions and extends to informal and non-formal learning arenas alike and expresses an imaginary that is obviously pertinent when the impacts of the SDGs on national curricula are to be considered.

The SDGs as a common good?

In the previous section, I suggested that the drafting process of Agenda 2030 and the SDGs may be productively considered from the perspective of curriculum theory. The concern has not been to claim that this UN endeavor reflects a curriculum process in itself, but to demonstrate Agenda 2030's significance as more than a passive background for UNESCO's follow-up in the global education policy of Education for Sustainable Development. In this section I elaborate on this while exploring a position that connects the SDGs with *the common good*, as this notion emerges within the UNESCO context.

In the UNESCO report *Rethinking Education: Toward a global common good?* (UNESCO, 2015), a key contribution is the consideration of education and knowledge as a global common good. With reference to Deneulin and Townsend (2007), the report states that the common good is “constituted by goods that humans share intrinsically in common and that they communicate to each other, such as values, civic virtues and a sense of justice” (UNESCO, 2015, p. 77). The notion of the common good is different from the notion of the public good in which human well-being is framed by individualistic socio-economic theory. From the common good perspective, it is not just the good life of individuals that matters but also the goodness of the life that humans hold in common (UNESCO, 2015, p. 78). Moreover, the weight on community is expressed in the emphasis on participatory processes that stand out as a common good in themselves.

In the UNESCO report the notion of education as a common good is contrasted with tendencies in current education policy to conceive learning as an individual process of skill acquisition with little attention paid to questions of the purpose of education and the organization of learning opportunities as a collective social endeavor. Furthermore, learning has been essentially centered on the results of educational processes and neglected the processes of learning (UNESCO, 2015, pp. 80–81).

While this perspective has bearings on how SDG 4 on quality education is considered, the emphasis on both education and knowledge may be seen as an invitation to mediate between this particular goal and the sustainable development agenda as a whole. The UNESCO report actually suggests such a mediation itself:

Given the central concern for sustainable development in an increasingly interdependent world, education and knowledge should thus be considered global common goods. This means that the creation of knowledge, its control, acquisition, validation, and use, are common to all people as a *collective social endeavor*. The governance of education can no longer be separated from the governance of knowledge.

UNESCO (2015, p. 80).

A major aspect of Agenda 2030 and the SDGs is definitely the governance of knowledge, consequently opening up for connecting the SDGs to the common good. While a conception of the SDGs as a common good is an intriguing, but complicated matter that cannot be sufficiently unpacked in this entry (see also Lotz-Sisitka, 2017), the relationship between the SDGs and the notion of the common good should be considered by revisiting the democratic impasse accounted for in *The democratic impasse* section above, particularly addressing community and membership.

As Lafferty (2012, p. 306) pointed out, nation-states as communities have historically been seen as delimited spatial units organized for self-governance, while sustainable development involves a notion of community based on ecological interdependence incorporating the interests of future generations, the world's poor, and the interests of other species. Connecting the SDGs to the common good accentuates this expanded notion of community, and demonstrates how goods that are intrinsically shared in common across borders, are under threat. As long as interests of the nation-states are determining political priorities, the impasse will remain.

With regard to membership, sustainable development implies that citizenship cannot solely be conceived of within the nation states, but is global in scope. In *Resolution 70/1 Transforming our world*, a vision of solidarity is distinctly stated in the preamble, "As we embark on this collective journey, we pledge that no one will be left behind" (United Nations, 2015), and SDG 10 *Reduced inequalities* particularly address the social, economic and political inclusion of all (United Nations, 2015). When the SDGs in such ways are connected with the notion of the common good, the contextual and processual character of this notion should also be considered. The UNESCO report *Rethinking Education: Toward a global common good?* proposes: "What is meant by the common good can only be defined with regard to the diversity of contexts and conceptions of well-being and common life" (UNESCO, 2015, p. 78). This proposal opens for considering the recontextualizations of the SDGs in various regional, national, and local contexts as aspects of the common good. If so, the perspective is definitely also pertinent to curriculum practices as accentuated by Schwab and Reid.

An emphasis on community and participation offers a critical perspective for empirical curriculum studies on the SDGs and on ESD initiatives. A decisive ethical and political concern is whose perspectives "are privileged in the curriculum as well as in education institutions more generally" (Apple and Buras, 2006, p. 3). Such a critical perspective may be conceived of as an immanent critique "of social practices using principles that are reconstructed from those very practices, rather than using principles that have their validity established by moral arguments that do not refer to the practices to which the principles are applied" (Stahl, 2019). Identifications of contradictions and impasses involved, as addressed in this entry, are instances of such an immanent critique, considering values and concerns expressed in the UN sustainable development agenda itself.

Most probably, the democratic impasse as posed by Lafferty (2012), still distinguishes processes within Agenda 2030 and the SDGs in the decade we have entered, and the reproductions of hegemonic structures and practices still take place in the recontextualization processes, and should be subject to critique within curriculum studies. However, as Benhabib has emphasized, claims made within structures like the United Nations that express an institutional cosmopolitanism may have mobilizing and transforming functions (Benhabib, 2011). A prime example of such a bottom-up initiative is the school strikes for the climate (Kvamme, 2019). Thus, Bengtsson's (2016) appeal to a logic of contingency in curriculum studies on education for sustainable development should be considered.

Conclusion

This entry has addressed aspects of curriculum, democracy, and the UN's sustainable development goals. A concern has been to demonstrate how the various perspectives in many respects are intertwined, transcending the borders of the nation-states, and calling for a multi-layered approach. Still, a deliberative position on curriculum practices and democracy has been adopted with an emphasis on the significance of context. In the final part of the entry, a major suggestion has been to connect the SDGs—including both the drafting processes, the UN Resolution 70/1 (United Nations, 2015), and subsequent recontextualizations—with the notion of the common good. Such a connection may premise critical studies of the curriculum processes that are promoted in the global education policy of ESD. Finally, let us return to Reid and a pertinent reminder that demonstrates how the global common good explored in this entry resonates with a curriculum theory that emerges from the local and the practical. "We are never going to realize perfect curricula, but schools, teaching, assessments, and mandates will only serve the good of society insofar as they are guided by curricular ideals" (Reid, 2006, p. 2).

Introduction

Rapid advances in digital technology and their pervasive adoption in all aspects of personal, social and workplace contexts have brought tremendous changes to the lives of citizens in all walks of life, and thus also the concept of citizenship. Digital citizenship as an area of study emerged around the turn of the millennium (Chen et al., 2021). Since then, there have been a lot of interest and development in this area of study from a diversity of disciplinary areas, including education, media studies, sociology, politics, and sociolinguistics. Public attention to digital citizenship as an integral part of the school curriculum started around 2007, coinciding with the publication of the first edition of *Digital Citizenship in Schools* by Ribble and Bailey (2007).

Conceptualizations of digital citizenship as an extension of the pre-Internet age construct of citizenship has been co-evolving in tandem with the rapid technological advances as well as the pervasive changes in personal, social, economic and professional practices in diverse contexts, be it local, national or global. This type of coupling and interaction, referred to as sociotechnical co-evolution (Geels, 2005), between technological innovations (such as in transport and energy industries) and a wide range of consequential changes in associated physical, technological, social, legal and cultural arenas have been observed in all cases where the technological innovation has brought about sustained social transitions.

Digital citizenship as part of the school curriculum has also been changing over time, though the scope of the change has been much narrower and slower compared to changes in the broader academic literature in this area. This article begins with an overview of digital citizenship and its variants in the school curriculum in different countries over time, which shows that much of the focus has been on digital competence, even though the influence of the Internet and social media on the social participation aspect of citizenship is starting to gain attention. Recent developments in digital citizenship curriculum conceptualizations have emerged from efforts of international organizations such as UNESCO, UNICEF, and OECD in connection with the concept of global citizenship (Chakroun and Keevy, 2018; Nascimbeni, 2019; OECD, 2019).

To gain further insight into the future development in the conceptualization of digital citizenship as well as policy and practice in digital citizenship curriculum, we further review the genesis in the conceptualization of citizenship over time since Aristotle. This is followed by a sketch of the more complex and nuanced conceptualizations of digital citizenship in the wider academic literature, as a consequence of the significant changes in how the Internet and social media have changed the landscape of sociopolitical action since the start of this millennium. The next section provides a brief overview of the citizenship curriculum within the broader educational and social context, highlighting its role in conserving the status quo and promoting the prevalent values and practices of the society. The final concluding section discusses the possible scenarios in the further development of the digital citizenship development based on a sociotechnical transformation perspective, highlighting the tension between the empowerment potential of digital technology for digital citizens and the conservative role of citizenship education in the curriculum.

Digital citizenship in the school curriculum

Citizenship has long been a part of the formal school curriculum in many countries, under different headings such as civics and citizenship education (e.g., Australia, [Moyle, 2014](#)), and often embedded within some school subjects such as social studies. Citizenship education generally focus on the rights and responsibilities of citizens within the specific socioeconomic, legal, and political context of the nation state within which the curriculum is situated. Hence, citizenship education has generally played the role of upholding (i.e., conserving) the status quo of the predominant culture and values of the nation state ([Subedi and Rhee, 2018](#)).

Digital citizenship has emerged as a distinguishable label in the formal school curriculum only in a few countries, e.g., Washington State in the US ([Tamayo, 2016](#)), Australia (e.g., the [NSW Department of Education, n.d.](#)), England ([South West Grid for Learning, n.d.](#)), New Zealand ([Netsafe, 2018](#)), and Singapore (referred to as cyber citizenship, [Singapore MOE, 2014](#)). An inspection of these curricula documents reveal that they share similar foci: ICT competence and related literacies, including the ability to address e-safety issues and for civic participation.

Digital citizenship as digital competence

The most influential definition for digital citizenship (DC in short) in the field of education is the one put forward by Ribble and colleagues through the three editions of a curriculum framework for digital citizenship ([Ribble and Bailey, 2007](#); [Ribble, 2011, 2015](#)) published by the International Society for Technology in Education (ISTE). This framework defines digital citizenship as “norms of appropriate, responsible behavior with regard to technology use” ([Ribble and Bailey, 2007](#), p. 10), and comprises nine dimensions grouped under three domains of a student’s everyday life: *digital access, digital learning, and digital communication* for learning and academic performance; *digital rights and responsibilities, digital etiquette, and digital security* as norms of behavior; and *digital health and wellness, digital law, and digital commerce* as necessary knowledge and skills for life beyond the school environment.

Ribble and colleagues’ competence-oriented DC framework has strongly influenced school curricula worldwide, as reflected by its citations as well as the commonality in content in curricula documents such as those discussed in the previous section. When DC is considered largely as digital competence, it is often considered as an integral part of a technology curriculum. For example, ISTE, a US-based professional society known for its influential technology standards for students, teachers and school leaders, has incorporated DC as one of the standards within the National Educational Technology Standards for Students (NETS.S, [ISTE, 2007, 2016](#)).

This competence-oriented conceptualization of DC is prevalent in more recent curricular frameworks, particularly those developed in the US, such as those by the DQ Institute¹ and Common Sense Media.² These newer frameworks tend to put more attention to the competence required by children and youth as their lives have become profoundly networked through the pervasive use of digital and social media. For example, Common Sense Media’s DC framework ([James et al., 2019](#)) has six topics: media balance and well-being; privacy and security; digital footprint and identity; relationships and communication; cyberbullying, digital drama, and hate speech; and news and media literacy.

While digital competence is widely acknowledged as important for the well-being of citizens, referencing such competence as digital citizenship is rare outside of US and Australia. The Council of Europe published a *Digital Citizenship Education Handbook* ([Richardson and Milovidov, 2019](#)), which is distinct from the Digital Competence Framework developed by the European Commission Joint Research Center ([Ferrari, 2013](#); [Vuorikari et al., 2016](#); [Carretero et al., 2017](#)). This will be further explored in a later section of this article.

Digital citizenship development requires social emotional learning

Similar to adults, children and youth are spending ever more time on digital devices and on the Internet. [James et al. \(2019\)](#) quotes statistics that show in the US, kids as young as age 5–8 spend on average almost 3 h per day on screen media, a third of which on mobile devices; and the time spent increases with age, with 45% of teens reporting being almost constantly online. Such extended exposure to the Internet and social media heightens the dangers due to cyber risks such as cyberbullying, identity thefts and data security breaches. While digital competence is needed to recognize and handle such risks, it is commonly recognized that social emotional learning is needed to cope with such challenges ([Datu et al., 2021](#)). There is a need for students to learn how to understand and manage emotions, to empathize and show respect for others, to establish positive relationships and make responsible decisions.

Social emotional learning is needed not simply to ensure e-safety, but to be able to live and contribute positively to a globalizing world. Socio-emotional competence is identified as one of the three core outcomes in the UNESCO Global Citizenship Framework ([Shin et al., 2019](#)) specified as “[having] a sense of belonging to a common humanity, sharing values and responsibilities, empathy, solidarity and respect for differences and diversity” (p. 75).

Evolving conceptualizations of citizenship in context

The two most prominent perspectives on digital citizenship as encompassed in school curricula worldwide are introduced above, focusing on digital competence and e-safety. Both are brought about by the necessity of living in a world permeated by the use of digital technology and are not directly connected with the concepts and practices in citizenship education in the traditional curriculum. Given that digital technologies have brought deep changes in the landscape of sociopolitical engagement and participation worldwide, it is inevitable that digital citizenship in this broader sense need to have a place in the school curriculum, whichever subject discipline or curriculum aspect it may be relegated to. To provide a solid foundation for understanding changes in digital citizenship in the broader academic literature, we provide here a brief introduction to evolving conceptualizations of citizenship in historical contexts.

Citizenship mainly refers to the obligational relationship between an individual and the larger community that the individual belongs to. From a political perspective, this larger community refers to the nation-state, and the individual is therefore citizen of the nation-state (Zajda et al., 2009). This concept of citizenship can trace its origin to the city of Athens at the time of Aristotle, when only one-third of the population were qualified to be citizens, and the remaining two-thirds were slaves. Thus, Aristotle was able to propose the noble concept that all citizens have the responsibility to bear office, i.e., to contribute to governing the city (Akinboye, 2015). With a small proportion of citizens in a small city such as Athens, Aristotle's utopian citizenship was a democratic one, as all political decisions could technically be made by counting the votes cast by all citizens. This democratic model, being coined as "direct democracy," has continued in some states or cities in Europe, such as Switzerland, with major political decisions decided by referendum (Wagschal, 1997). It has to be noted that the citizenship concept further developed along with the elimination of slavery such that every individual is empowered to become a citizen of the state. Thus, the concept of citizenship grows alongside liberty, freedom, entitlement to social welfare, and most importantly equality and the right and duty of participation, especially active participation in civil affairs (Lee and Fouts, 2005).

The concept of citizen-state relationship was consolidated by the evolvement from the landlord system to the nation-state, and at that time, the concepts of nation and state were basically equivalent to each other, as for most of the cases at that time, one nation-one state. Thus, the dominant concept of citizenship was represented by national citizenship (Axtmann, 2004; Mandelbaum, 2013). It was only quite recently that the concept of supra-national citizenship emerged with the formation of the European Union. Many individuals want to identify themselves as European citizens, in addition to being citizens of a European country. This is especially apparent after the breakdown of the Communist bloc in Eastern Europe. Many Eastern European countries went through a democratization process and joined the European Union. Thus, individuals from these Eastern European countries particularly welcomed the identity of being a European citizen (Baubock, 2007).

The notion of national citizenship is challenged when the concept of citizenship is applied beyond the state to a larger entity such as Europe, giving rise to the concept of post-national citizenship (Tambini, 2001). Coupled with increasing international events and interactions in diverse, multiple domains, including economic, financial, cultural, and sports, this led to the emergence of global citizenship. Advanced transportation technologies have also contributed to the emerging prominence of global citizenship by enabling people to travel, which is one of the factors contributing to phenomenal mass migration, and the rise of cosmopolitan cities characterized by constant inflow and outflow of its population (Osler and Starkey, 2003). Some inhabitants of cosmopolitan cities are short-term residents, who may be laborers shouldering jobs not taken by the locals, or professionals residing as expatriates. They may not be citizens of the nation state, but they make significant contributions to the city and/or state where they reside. The concepts of resident and citizen thus become blurred if active participation is an important criterion in defining citizenship (Sadiq, 2008). The increasing uptake of the concept of global citizenship is also due to the increasing awareness that our behavior will not only affect those close to where we stay, but also the wellbeing of others in far corners of the world, and that issues of environmental protection and sustainable development can only be resolved through concerted global action (UNESCO, 2014).

Alongside with global citizenship emerged the concept of global competence, the attributes of which include openness to diversity and differences, ability to interact and communicate with people from different cultures and holding different ideas and values, with appreciation and respect. Global competence is considered important for generating new knowledge and novel solutions to unknown situations, and became a theme for comparative assessment of student competence in PISA 2018 administered by OECD (OECD, 2018).

Broadening of the concept of citizenship from nation-state, i.e., national, to post-national, supranational, and global levels indicates that citizenship rights and responsibilities are no longer confined to one's political affiliation, but to the communities that one relates to. Even at the national level, according to Anderson (1983), state is a rather abstract concept to most civilians, as unlike the Athenian times, it is impossible for people in large states with large populations to relate to each other on a daily basis. The concept of imagined communities is important for the extension of citizenship affiliation to broader communities beyond the nation-state toward post-national, supranational, and global communities.

Digitalization has become a fast growing and powerful platform for people to connect through multiple forms of interactions—at personal level, social and organizational levels. It has also infiltrated into the fabric of our everyday life in almost every sector: educational, economic, sociopolitical, cultural, etc. The digital world has become another space for global actions and interactions, giving rise to the concept of digital citizenship, which shares some of the characteristics of global citizenship. Indeed, the number of "inhabitants" on some of the social media platforms such as Facebook (the total monthly and daily active users are 2.6 billion and 1.73 billion respectively according to OBERLO (2020)) are even bigger than the size of the most populous country. For

many people, the digital communities they belong to are crucial to defining who they are, what they do, and their personal identity. Thus, it is meaningful to consider digital citizenship as an extension of citizenship in its full social, political, and cultural richness.

Digital citizenship for civic, political and economic participation

Grounded on the traditional association of citizenship with membership of geopolitical entities such as nation states, Marshall (1992) defined citizenship as “the right to share to the full in the social heritage and to live the life of a civilized being according to the standards prevailing in the society” (p. 74). Based on this definition, citizens are bestowed with rights in multiple domains: civil, political, and social. Cogan (2000) identifies five categories of citizenship attributes, which have been commonly accepted: sense of identity, enjoyment of specific rights, interest and involvement in public affairs, fulfillment of relevant obligations, and acceptance of basic social values. Digital technologies, in particular the Internet and social media, challenges a geographically bounded conceptualization of citizenship as people increasingly connect and interact with people and issues that may not even be locally relevant.

Digital participation as citizenship rights

Mossberger et al. (2007) put forward a conceptualization of digital citizenship as an extension of citizenship, defining digital citizens as “those who use the Internet regularly and effectively,” and digital citizenship as the “ability to participate in society online” (p. 1). This conceptualization focuses on three areas of digital participation: regular and effective use of prevailing forms of digital communication; participation as democratic citizens through the Internet; and the ability to take full advantage of job market opportunities via the Internet. Similar to Ribble and colleagues, Mossberger et al. (2007) also perceive digital citizenship as ability, but the focus is on equity. Their studies show that Internet use brings benefits to the individual as a conduit for social, political, and economic participation. They further provided empirical data that show digital participation ability is not simply a matter of competence but influenced strongly by pre-existing inequities such as socioeconomic disadvantages (lack of access to the Internet at home and in other settings) and racial inequalities.

While Mossberger et al. (2007) focus on digital participation includes civic and political participation, they did not take on a critical perspective when considering the citizen as a political subject. Political participation was considered within existing frameworks of democratic rights of participation of the nation state. However, just as historically civic and political participation of citizens is often not confined to prevalent legal and political frameworks, the same is true of digital sociopolitical participation. The prevalence of the Internet and social media has brought fundamental changes and challenges to civic and political participation as well as national and international politics and governance.

The rise of DIY citizens and borderless netizens

Law (2021) identified two major roles played by technology in the social creation of knowledge: augmenting human performance and connecting minds over time and space. The impact of these two features of the Internet and social media is evident in the evolution of digital participation since the turn of the new millennium. The accessibility of sophisticated technologies such as powerful search engines, global networks of communication and multimedia production software suites at low (or no additional) cost and low competence thresholds to the average person, especially those in developed economies has led to the phenomenon of “DIY citizenship.” The term “DIY citizens” was coined by Ratto and Boler (2014) to refer to individuals and groups who engage in civic/political actions to challenge and transform the status quo through online and offline means.

The concept of global citizenship (Falk, 1993) emerged before the popularization of the Internet, due to advances in transportation and communication technologies as well as increasing migration across countries and regions. Globalization and transnational cooperation created international/regional systems of rights, civil societies and public spheres that are not coterminous with the nation state, race or culture (Habermas, 1994). Dahrendorf (1994) put forward a framework of rights that transcends the nation state, comprising two dimensions: basic rights (human rights, civil rights and democratic political rights) and enabling rights (social rights such as social services and welfare to ensure that people have the capacity to exercise their basic rights).

The rise of social media has brought about more self-actualizing forms of citizenship. The Internet serves as the space for public engagement, and online network communities provide the sociotechnical infrastructure for propagating ideas, values, and norms as well as for supporting DIY organizational processes. Through various digital means, individuals are now able to choose or form their own online communities and hence their own “citizenship,” and to be more self-determined in their political perspectives and decisions.

Internet activism and place-based social action

Internet and social media bring new possibilities and challenges to democratic social participation. Neumayer and Rossi (2016) reviewed research literature on Internet/social media activism over the 15 years from 2000 to 2014, and identified changes over three dimensions: technology used, geographic location and nature of the activism. At first, the technologies used were referred to in general terms, such as Internet or cyberspace, but later references pinpointed the use of specific technology platforms, such

as “Facebook revolution” and “Twitter revolution.” Until 2008, most of the activism movements focused on US and Canada. From 2009, such activism emerged in places beyond North America, such as in Iran (where the first Twitter revolution took place), the Middle East (the Arab Spring), and China (the Occupy Central in 2014 in Hong Kong). There was also a distinct change in the nature of the activism that emerged, starting from a concern with long standing societal issues such as environmental, human rights, and racial justice to networked political activism that are specific to the local/national context such as the Arab Spring, Indignados and the Occupy movements.

In the early days of the Internet, cyberspace was conceptualized as distinct and separate from the world of physical interactions. *Life on the screen*, as Turkle’s (1995) research showed, provided an escape, an alternate reality for those who have the privilege of access to the Internet, which tended to be staff and students in colleges, universities and research lab in those days. Life on the screen was a separate existence from real life, and inhabitants in cyberspace had a separate virtual identity, often distinct from their identity known to family, friends, and co-workers.

When Turkle wrote her book *Alone Together* (Turkle, 2017), the scenario had totally changed. Talk about computers and the Internet was happening around kitchen tables and playrooms, and people, young and old, were inextricably connected to each other via different kinds of technology-enabled communication from text messaging to video calls to social media platforms. This kind of tremendous change taking place over a short period of 15 years was to a large part prompted by the popularity and accessibility of smartphones, which have become the most convenient channel of Internet access. This has also contributed much to connecting Internet activism to place-based social action.

Gerbaudo (2012) described a “choreography of assembly” (p. 5) orchestrated through skillful integrated use of media and technologies to connect the (cyber)space and place of social action. Social media tools can be used to spread awareness about a movement, broadcast/share information about meetings, rallies, and events, and attract further public attention through national/international news and mainstream media. The Twitter hashtag has become an important tool to connect disparate groups sharing a common cause to rally together. Smartphones with their location aware/location tracking feature serve as a perfect tool to orchestrate offline network activism. Sandoval-Almazan and Gil-Garcia (2014) described a 4-step model of political activism using digital technology: triggering event, media response, viral organization, and physical response. The first three steps take place primarily through the Internet, but the ultimate goal is to rally large numbers of place-based in-person participation in physical protest actions.

Through researching and interviewing key activists involved in three large scale Internet-based political movements that took place in 2011 (the Arab Spring in Egypt, the Spanish indignados, and Occupy Wall Street in New York), Gerbaudo (2012) concluded that social media use play a complementary role to existing forms of f2f interactions and on-street protest actions. Further, such social actions are not leaderless, as often claimed, but leadership is hidden through social media administrators and through the hierarchical nature of social networks in which a few people commands an inordinate amount of influence. However, the mode of communication with the leadership is changed. Organization becomes more fluid, following the communication channels, rather than the other way around as in traditional organizations, and participants communicate directly with the organizers through messages rather than orders.

Tensions between empowering/empowered digital citizens and the (digital) citizenship curriculum

In **Digital citizenship for civic, political and economic participation** section, we have highlighted how digital technology, particularly the Internet, social media, and the pervasive ease of access to smartphones have helped to facilitate grassroots political action of massive scales and the perils of disinformation. The empowerment effects of digital technology stand in contrast to the role played by citizenship education in promoting dutiful citizenship (Bennett, 2008). Citizenship education serves to support students’ assimilation into the mainstream culture and foster national belonging (Banks, 2007).

There are many ways to enact dutiful citizenship in the curriculum. Curriculum is a broad concept, and there are varied approaches. The first and most widely adopted approach is to consider curriculum as an organization of study, defined in terms of a set of subjects, a set of materials, a sequence of courses, a course of study, and/or a set of performance objectives, often referred to as syllabus, content outline, textbooks, etc. As an organization of study, curriculum can also be viewed as a process, referring broadly to school activities as a series of learning experiences—academic, athletic, emotional and social—in the school context (Oliva, 1992; Marsh, 1997; Posner, 1998). A second approach is to conceive curriculum as a learning orientation in response to the perceived overarching educational goals to be achieved. For example, Longstreet and Shane (1993) identify four types of curriculum orientations, namely society-oriented curriculum, student-oriented curriculum, knowledge-oriented curriculum, and eclectic curriculum. The latter looks at curriculum from the broadest possible perspective that involves various compromises related to the purpose and process of teaching and learning. A third approach focuses on classifying curricula based on how they are operationalized in schools. Esiner (1994) classifies school curricula into the formal (or official) curriculum, implemented curriculum, and hidden curriculum. The hidden curriculum is well known for its close relationship to citizenship education as it transmits implicit social norms and political expectations as a part of school life. MacDonald (1977) suggests that the curriculum plays a mediation role between the individual and the societal order and the political order, through a process of internalization developed from school experience.

By discussing curriculum in broader contextual terms, its linkage to citizenship education becomes more salient, especially in its social reconstructionist functions. It is particularly important to note that curriculum can be invisible and intangible, subsumed in

school life and in the society's social and political atmosphere that both teachers and students experience every day. Williams (1976) further argues that the school curriculum, including the hidden curriculum, is not ad hoc but intentionally selected, though often in a tacit manner, on the basis of a larger culture (Giroux, 1981). A whole possible area of past and present, certain meanings and practices can be chosen for emphasis, while certain other meanings and practices can be neglected and excluded. In this way, schools become agents of cultural incorporation, initiating the younger generation into selected cultural traditions. Giroux (1981) concedes that school is reproductive in the cultural sense, functioning to distribute and legitimize forms of knowledge, values, languages, and modes and styles of social etiquette that constitute the dominant culture and its interests. Freire (1974) further points out that education is a means of cultural action and schooling functions as a system of communicating a particular cultural message.

This broader perspective toward curriculum, referred to as the "institutional or policy curriculum" (Doyle, 1992a,b), describes the connection between schooling and society, embodying a conception of what schooling should be with respect to the wider society and culture. In situations when social and cultural contexts change rapidly, the institutional curriculum serves a mediating role between schooling as a socialization tool of the nation-state according to prevalent norms and responding to the changing expectations from stakeholders outside of schools, such as parents, employers, and socio-cultural agents. What we wish to highlight here is that this mediation role has two implications: (1) the institutional curriculum (including the citizenship curriculum, whether formally defined and implemented or as part of the hidden curriculum) will co-evolve over time as social norms and institutions change, and (2) there will be tensions experienced by school leaders and teachers in this process of mediation due to differences in expectations within the school community and with those held by the wider society. This tension is evident in examples of within campus conflicts and participation of students in internet-mediated political activism mentioned in **Digital citizenship for civic, political and economic participation** section. In the Anti-extradition Bill social movement that started in June 2019 in Hong Kong, we see children as young as 11-years-old participating in on-street protests and riot activities as well as occupation and vandalism of university campuses that were orchestrated through the Internet. Schools were also victims of the intensifying polarization in the community, with some facing intense criticisms from some sectors of the community due to the stance and participation of their teachers and students in the social movement. These tensions expose the conflictual role of citizenship curriculum: whether to function as enculturation or critical enculturation. The former is required for social solidarity, whereas the latter is often regarded as important for social progression as testified in the historical development of many countries.

The future of digital citizenship curricula

Throughout history, technological inventions from cavemen paintings to printing, telecommunication, to modern day digital technology has played instrumental roles in transforming human learning through augmenting human performance, providing more powerful ways of knowing, and connecting minds over time and space (Law, 2021). However, the adoption and impact of such technologies, and in particular whether these have really empowered learners in schools and classrooms have never been a simple matter of technology adoption.

Sociotechnical regime challenges in the context of educational transitions

Education is a sociotechnical system, and parallels can be drawn with other similar systems such as transportation and e-Government systems to help us consider the relationship between digital technology, digital citizenship, and the curriculum. Sociotechnical systems involve the integration and adoption of technology systems into organizational and social settings, and their successful deployment cannot be achieved by simply focusing on the technological perspective, without regard to the social and organizational aspects (Cherns, 1976). Geels (2005) analyzed how automobiles took over horse-drawn carriages as the dominant means of urban transport, which shows that the invention of the internal combustion engine around 1860 was only one step in that transition process. To transform the entire transportation system requires changes in the user practices, infrastructures, markets, maintenance networks, production systems, cultural/symbolic meanings, and public policies, etc. connected with the then predominant horse-drawn carriages transportation system to the corresponding ones for transportation systems centered around automobiles. These interconnected and interdependent systems associated with a sociotechnical system is referred to as sociotechnical regimes (Geels, 2005) e-Government is another example of a sociotechnical system. Abunadi and Alqahtani (2019) studied the sociotechnical factors influencing the acceptance by online users of e-transactions in e-Government systems in Saudi Arabia. They identified four key challenges, all belonging to the sociotechnical regime domain in user adoption of e-transactions: a lack of computer literacy and Internet access, an urban-rural digital divide in the availability of adequate technological infrastructures, a lack of public awareness of the available e-services, and inadequate legislation for e-transactions as an official means of conducting business. Based on their empirical findings, Abunadi & Alqahtani (Abunadi and Alqahtani, 2019) recommended changes to the technological, organizational (including policy), and social systems associated with e-transactions to address these challenges.

Integrating digital technology use into education systems is no less challenging and complex compared to the two sociotechnical system changes described above. Despite decades of strong policy directive in many countries to actively promote the use of information and communication technology (ICT) to foster the development of 21st century skills (Plomp et al., 2009), the overall findings have not been positive (e.g., Collins and Halverson, 2009). It is well documented in the technology-enhanced learning literature that deep changes need to take place in teachers' practices far beyond the mastery of technical skills (Albion and Tondeur,

2018). The vision of educating students to become lifelong learners capable of creative problem solving in collaboration with peers is a fundamental shift from the goals of universal education in the industrial era (Collins and Halverson, 2018). Collins and Halverson (2018) elaborated on the barriers to technology use in school and argue that many of the obstacles reflect deep incompatibilities between schools and the transformative visions of technology use in education. Using Geel's (2005) sociotechnical change analytical framework, Law and Liang (2019) show that even when pedagogically innovative technology adoption successfully emerges under conducive policy level support, for example, when digital technology becomes embedded into student-centered curriculum practices, the sustainability of the innovation may still be fragile. For emerging e-learning practices to become mainstream requires community-wide changes in the curriculum outcome goals embraced, as well as continuous adaptations in school routines, curriculum content and structure, forms and foci of assessment, technological and human resources infrastructure and priorities, as well as ways of working with other stakeholders such as parents and community partners, all of which are interconnected and interdependent elements of the sociotechnical regime within any education system.

The sociotechnical changes to education brought about by digital technologies is not only enhancing students' access to online learning, but also playing an increasingly significant role in students' socialization, which is a significant function of the education system, especially citizenship education. Properly recognizing the socialization role of digitalization will necessitate the integration of digital citizenship into the curriculum. In the previous section, we highlighted tensions between empowering/empowered digital citizens and the DC curriculum. Such tensions can be further examined within the broader context of sociotechnical change. On the one hand, for digital technology to realize its transformative educational potential requires sociotechnical regime level changes toward more student-centered pedagogy, more open, exploratory, and inquiry-oriented curriculum, and more democratic, non-hierarchical school culture that gives voice to all individuals. On the other hand, the (digital) citizenship curriculum is an integral part of the overall school curriculum, and generally serves an important role as a socialization tool of the nation-state to preserve the status quo according to prevalent norms. The prevalent focus on digital competence and socioemotional wellbeing in current digital citizenship curricular reflects an empowerment orientation. However, it is also evident that the empowerment is predominantly oriented toward the learners' personal and social wellbeing at an individual level, leaving the social political engagement aspects of citizenship education relatively untouched. There is little evidence that the DC curriculum has reflected the changing conceptualizations and debates around DC beyond technological competence. Such a situation is not surprising from a sociotechnical change perspective, as the development of a DC curriculum catering for social political participation in the digital era is a sociotechnical regime level change which is much more challenging. However, we also argue that this under-development is highly undesirable, and may cause serious ramifications to stability at the sociotechnical regime and landscape levels, as will be elaborated in the remainder of this section.

Need for continuity between citizenship and digital citizenship education

Choi (2016) identified four key categories of DC conceptualization through a systematic conceptual analysis of the literature: ethics, media and information literacy, participation and engagement, and critical resistance. The first two categories are the key foci in existing DC curricula as discussed in the **Digital citizenship as digital competence** section. The third category, participation and engagement (P&E), comprises two forms of engagement—macro and micro. The micro (or personalized) forms of DC engagement refers to interest-driven online activities, including games, popular culture, various forms of self-expression, and entertainment related activism as a form of civic engagement. This category of digital engagement is also increasingly addressed in some DC curricula that supports e-safety and social emotional learning as described in the **Digital citizenship development requires social emotional learning** section. Macro forms of DC engagement refers to ways of using the Internet as an extended sphere for political participation, which includes e-voting, online petitions for political/economic causes, and online electioneering. While macro forms of P&E addressed within the scope of traditional citizenship curricula remain conservative, these are not even included as a topic under existing DC curriculum at the school level.

Whereas P&E in Choi's (2016) DC conceptualization focuses on online participation that are legitimate under existing systems, the critical resistance category pursues more progressive and radical means and outcomes, through critique of existing power structures and/or political activism, as described in the **Internet activism and place-based social action** section on internet activism and place-based social action. Critical resistance is not a theme even under the traditional school curriculum. It can be argued that this is perfectly reasonable since an important role of education as an integral part of the sociotechnical regime is to preserve the existing sociopolitical system and values. On the other hand, there are many examples in the history of scientific and technological advancement, such as nuclear reactions, in which the operations and consequences of powerful inventions fail to be deliberately and systematically controlled. Regarding Internet technology and education, Glassman and Burbidge (2014) warn of the risk of "ceding control of the Internet's relationship with education to small, entrenched populations attempting to control rather than expand possibilities" (Glassman and Burbidge, 2014, p. 17). It is important for the wellbeing of our society that our younger generation have the opportunity to understand the possibilities that digital technology, and in particular digital social media, brings to socio-political participation, as well as the threats that these may pose to upholding the core values of social justice and democracy. In an in-depth action research on how a grassroots movement appropriates a variety of digital and social media tools for their science activism, Ghoshal and Bruckman (2019) showed that there are values embedded in the technology systems deployed, and that the core values of inclusivity, privacy/security, and social translucence are given different priorities by different technology tools. Proprietary owners of social media platforms and power users making decisions on the choice and set up of digital technologies

for P&E have advantaged access and influence that could jeopardize the very core values that participants in (place-based connected) digital social movements strive to uphold.

Place-based citizenship, global awareness and global citizenship, and digital citizenship are connected facets of one's dialectic interactions with the social, political, and digitally connected world. One notable effort in bridging these different facets of citizenship is the Digital Citizenship Education (DCE) framework developed by the Council of Europe (Richardson and Milovidov, 2019). The DCE framework comprises 10 domains categorized under three themes: (theme 1) being online—access and inclusion, learning and creativity, media and information literacy; (theme 2) well-being online—ethics and empathy, health and well-being, e-presence and communications; and (theme 3) rights online—active participation, rights and responsibilities, privacy and security, and consumer awareness. Within this framework, children as citizens have the right to both protection and participation, and the competences to be developed within the 10 domains are explicitly connected to active engagement and participation, underpinned by the core values of human dignity and human rights. The framework (Richardson and Milovidov, 2019) also puts forward a “five-pillar” model for its implementation. Four of the pillars are sociotechnical regime level elements: policies, strategies, infrastructure and resources, and evaluation, and the fifth pillar is multi-stakeholder engagement. This framework addresses the discontinuity between traditional citizenship education and the concerns prevalent in digital citizenship curricula and takes account of the need for regime level changes for its realization. Hopefully, there will be more efforts to extend DC curriculum along these two directions.

Summary

Digital citizenship in the school curriculum has been changing over time, but is still primarily confined to digital competence and e-safety/cyber wellness. Inclusion in the school curriculum regarding civic or political engagement and participation through using digital technology is still rare. This contrasts with the more complex and nuanced changes in the conceptualizations of digital citizenship in the wider academic literature to take account of the deep changes in the landscape of sociopolitical engagement and participation worldwide brought about by the use of digital technologies. Citizenship mainly refers to the obligational relationship between an individual and the larger community that the individual belongs to. For a long time, citizenship was synonymous with nation-state citizenship. With increasing mobility across countries and regions due to advances in global transportation systems and sociopolitical changes in many parts of the world, nation-state citizenship has been broadened to include post-national, supranational, and global citizenship. The digital world has become another space for global actions and interactions, and it is important to consider digital citizenship as an extension of citizenship engagement in holistic perspectives embracing its full social, political, and cultural richness. Social media platforms have complemented existing forms of face-to-face interactions and on-street protest action in a “choreography of assembly” (Gerbaudo, 2012, p. 5) to connect the (cyber)space and place of social action. The traditional focus of citizenship education on promoting dutiful citizenship is inadequate in addressing the tensions and challenges created by the empowerment effects of digital technology, as evidenced by the examples of within campus conflicts and participation of students in internet-mediated political activism. Digital citizenship education needs to take on the responsibility of ensuring that children and youth have the right to protection and participation by empowering students with appropriate competence, attitudes, and values for their digitally mediated participation to contribute to enhancing personal and social wellbeing.

Children's rights: part of democratic practice?	429
Summary and conclusions	431
References	431

We conceive of democracy as embedded in participation and deliberation, with a strong emphasis on the participatory rights in the CRC (United Nations Convention of the Rights of the Child, 1989). These rights include a child's right to expression, the child's right to an opinion given due consideration by adults, access to appropriate information and to freedom of association; all in accordance with the age and maturity of the child. In our research projects, children are recognized as agents in society, not as immature objects to be excluded from deliberative and other political processes. The opportunity to be respected members of the public discourse provides young citizens with real life experiences that enable the development of language and reasoning skills, and especially skills in perspective taking and critical thinking that are fundamental to the actors in an equitable and sustainable democratic society

Carlson et al. (2002, p. 39).

This quote, focused on democracy and children in Costa Rica nearly twenty years ago, is a good place to start the discussion of democracy, curriculum and childhood for young children. It is clear that although the United Nations Convention on the Rights of the Child (UNCROC) (United Nations, 1989) is a very important piece of legislation in the signatory countries, whether the focus on children's rights has translated into children having agency and a recognized "voice" in how the curriculum in their educational setting is enacted is paradoxically another issue. This chapter will begin with some definitions of curriculum and how they enable understandings of democracy in the early years. Then some of the ideological underpinnings of curriculum are explored in relation to curriculum approaches. The different types of curriculum are critiqued to see whether they are fit for purpose for supporting children to become democratic citizens of a society. Finally, the chapter explores the notion of children's rights in relation to democracy and what is needed to enable children to become democratic citizens in the early years.

Definitions of curriculum and democracy

It is arguably useful to start any discussion of early childhood curriculum and democracy with some analysis of what a democracy is and how it might be related to early childhood settings. Sources used are both seminal and contemporary, drawing on internationally published scholarly theoretical and empirical research and some commissioned reports, such as those by OECD. A search for relevant literature in library databases and gray literature was conducted using the search terms curriculum, curricula, democracy and early childhood education. Where possible, evidence-based sources have been drawn on. Because the author is a New Zealander, some examples are drawn from New Zealand to illustrate key points.

Democracy

In a seminal argument, Cohen (1971) proposed that a democracy is a community in which everybody has the opportunity to influence decisions that are of importance to them. He argued that the ways citizens participate, inhabit, negotiate, and challenge the given conditions for participation indicate how democratic their situation is. According to Cohen (1971), different ways of participating, both quantitatively and qualitatively, indicate the breadth, depth, and range of democracy. Democracy can be expanded by widening community input into these factors. For early childhood communities, this notion would therefore concern how many people influence decision making, what level of involvement different individuals—including children—have, and who has authority to make decisions. Participation is the key concept, and it is one which becomes problematic when children are not defined as citizens with agency in the early childhood setting (Einarsdottir and Wagner, 2006; MacNaughton, 2007).

However, while Cohen (1971) relates democracy primarily to participation, he does not problematize the values that are interwoven in the ways of participation. Biesta (2011) argues that democratic participation needs reference to democratic values, and this is a point of connection with some early childhood curricular internationally (Einarsdottir et al., 2015). Moss (2011) provides a helpful twofold characterization of democracy and education as inseparably interconnected: democracy as a basic value and

practice in education; and education as a means to strengthen and sustain democracy. This is clearly something that can be promoted through engagement with young children in early childhood contexts.

For Held (2006, p. 1), democracy *prima facie* means “a form of government in which, in contradistinction to monarchies and aristocracies, the people rule. Democracy entails a political community in which there is some form of political equality among the people”. However, he also acknowledges the complexity of the topic and the potential for disagreement over definitions (Sousa and Oxley, 2019).

Although democracy is not the principal reason that early childhood education is advocated in many countries, the ability to be a good citizen is. Indeed, developing contributing members of society is one of the key arguments for investing in early childhood (Heckman, 2012; Heckman and Masterov, 2007). The arguments around this stem primarily from an economic analysis, not a values based one, but the outcome of having well educated members of a society is intertwined and investment provides strongest outcomes for the most disadvantaged children. As the noted economist, Heckman (2012) argues:

The highest rate of return in early childhood development comes from investing as early as possible, from birth through age five, in disadvantaged families. Starting at age three or four is too little too late, as it fails to recognize that skills beget skills in a complementary and dynamic way. Efforts should focus on the first years for the greatest efficiency and effectiveness. The best investment is in quality early childhood development from birth to five for disadvantaged children and their families.

Many nations have understood the need for economic investment in their youngest children, as part of increasing equitable outcomes for all children and thereby demonstrating principles of democracy. For example, the policy document that drove major change in early childhood education in New Zealand “*Education to be more*” (Department of Education, 1988) cites the outcomes of early childhood education as increased educational achievement and reduced need for special education, increased likelihood of employment, reduced delinquency and teenage pregnancy and an economic outcome of paying for itself by saving the taxpayer \$400–700 for every \$100 spent on early childhood. The rationale underpinning these documents was therefore twofold: early childhood education was defined in economic terms as having long term benefits for children, families; and ensuring the state’s goals for the economy were achieved. The government had two goals: to equip New Zealanders with 21st century skills, including democratic citizenship; and to reduce systematic underachievement in education; sometimes known by the catch phrase “raise achievement and reduce disparity” (Adams and Bethell, 2005, p. 144). However, achieving these outcomes came with a price tag: the introduction of a “charter” for licensed early childhood services, which mandated increased accountability and government control via licensing through the newly formed Ministry of Education and review via its quality assurance arm, the Education Review Office.

John Dewey is often cited as a key advocate of democracy as an outcome of education. Dewey (1916) argued that children learn about being a citizen through engagement with projects which challenge them to understand diverse perspectives. Central to Dewey’s educational thinking was the idea that project-based enquiry could engage learners with the knowledge needed to sustain a process of reconstruction (Dewey, 1916). He proposed that inquiry-based learning would help children develop and to overcome the dualism that may exist between the child and the curriculum and the school and society. In such a way, the curriculum is made relevant and meaningful to children, their previous experiences, and their life contexts. As Dewey proposed “the teacher should be occupied not with subject matter in itself but in its interaction with the pupils’ present needs and capacities” (Dewey, 1916, p. 191). Dewey argued that by involving children in learning things that are of interest to them and giving them choices about what they learn helped children to learn the link between education and a democratic and participative way of life. This principle of allowing children to select the focus of their learning and the pace and sequence of early childhood curriculum is part of many early childhood curriculum and is explored next.

Definitions of curriculum in relation to democracy in early childhood education

Curriculum is a complex concept influenced by various factors that reflect a society’s political, policy and technical consensus on the goals and values regarding children’s learning, development and well-being (Litjens and Taguma, 2010). According to Scott (2008), “A curriculum may refer to a system, as in a national curriculum; an institution, as in a school curriculum; or even to an individual school, as in the school geography curriculum” (pp. 19–20). According to Scott (2008), a curriculum can be organized specifically to include four dimensions:

aims or objectives, contents or subject matter, methods or procedures, and evaluation and assessment. The first dimension refers to the reasons for including specific items in the curriculum and excluding others. The second dimension is content or subject matter and this refers to knowledge, skills or dispositions which are implicit in the choice of items, and the way that they are arranged. Objectives may be understood as broad general justifications for including particular items and particular pedagogical processes in the curriculum; or as clearly defined and closely delineated outcomes or behaviours; or as a set of appropriate procedures or experiences. The third dimension is methods or procedures and this refers to pedagogy and is determined by choices made about the first two dimensions. The fourth dimension is assessment or evaluation and this refers to the means for determining whether the curriculum has been successfully implemented (pp. 19–20).

Thus, the four crucial elements which apply to curriculum in relation to building democracy include the following:

1. *Aims, goals, objectives or outcome statements*—what do we want this curriculum to achieve in terms of children and democracy, what would we expect to be the outcomes in terms of democracy as a result of participating in the implementation of this curriculum?
2. *Content, domains or subject matter*—what will we include or exclude from our curriculum to understandings of democracy and democratic practice?
3. *Methods or procedures*—what teaching methods or approaches will we use to achieve these goals and values of democracy?
4. *Evaluation and assessment*—how will we know when we have achieved them?

Scott's (2008) definition is obviously broad, and it equally applies to many levels of the education system. However, what a community expects its education system to achieve is a strong force in determining curriculum content. As the OECD (2018) state, a curriculum framework is an over-arching document that articulates the broad vision of curricula within the broader context of the education system. As the OECD (2018) argue, not all curricula or curriculum frameworks present a clear theoretical foundation of a particular pedagogical approach. Rather, some are broad and can embrace varied pedagogies. Curriculum is a crucial agent of education policy as it deliberately specifies what is valued for a particular level of education, potentially including learning objectives, content, methods (including assessment) and materials for teaching and learning, as well as arrangements for teacher training and professional development (OECD, 2018; Sylva et al., 2016). Therefore, in terms of promoting democracy through education, a country's community and its government will make key decisions about what role democracy plays in the curriculum of young children in local, regional and national communities, although there may be marked differences among communities within a nation.

According to the OECD (2018), curriculum is "a political, policy and technical agreement among the various institutions and stakeholders, from both inside and outside the education system, on why, what, how, when and where to educate and learn" (in OECD, 2019, p. 10). Within this definition, curriculum can be described as "intended", "implemented" or "achieved". The intended—also official or planned—curriculum specifies what authorities and society expect students will learn at school and how the outcomes of the teaching and learning process will be assessed. The implemented curriculum, also defined as the "taught curriculum" or "curriculum in action", is the "actual teaching and learning activities taking place in schools through interaction between learners and teachers as well as among learners" (OECD, 2019, p. 10). Finally, the achieved curriculum may differ from the intended and implemented curriculum as it "indicates what learners actually acquire as a result of teaching and learning, assessed through different means and/or demonstrated in practice" (OECD, 2019, p. 10).

In addition to the notions of intended, implemented, and achieved curriculum, Bernstein (1996) argues that there are essentially two models of curriculum and that all curricula fall into one or the other category. He states that curriculum is oriented to either *performance* or *competence* and that *performance* models of curriculum are the most dominant around the world. The *performance* model has its origin in the behavioral objectives' movement. It is a model that clearly emphasizes marked subject boundaries, traditional forms of knowledge, explicit rules for pedagogic practice and strong boundaries between different types of students (Scott, 2008, p. 4). In contrast, the *competence* model suggests that learners have some control over the selection, pacing and sequencing of the curriculum, echoing Dewey's (1916) notions of children being able to make choices to learn about what interests them. Competence models have been more common in early childhood education, such as in the early childhood curriculum of Australia and New Zealand (DEEWR, 2009; Ministry of Education, 1996, 2017), while some curriculum models also clearly promote notions of agency and democracy as part of early childhood curricula (Einarsdottir and Wagner, 2006). However, the dominance of competence models of curriculum in early childhood education is changing in some countries; the *Foundation Stage* curriculum in the UK (Aubrey, 2004; Standards and Testing Agency, 2016), for example, has clearly defined curriculum outcomes and achievement standards for very young children.

Using Bernstein's (1977) notion of classrooms as message systems—consisting of curriculum, pedagogy and evaluation—Munns and Martin (2005) argue that such message systems operate within "discourses of power", especially discourses around knowledge, ability, control, place and voice. They argue that these issues influence the ways in which teachers and learners view themselves in the classroom. They propose that the following questions need to be answered about the curriculum:

- What counts as knowledge and who has access to really useful knowledge?
- Who has ability?
- Who controls the teaching space?
- Who is valued as an individual and a learner?
- Whose voice is given credence within that space?

Munns and Martin (2005) argue that historically students from poor backgrounds have received disengaging messages about their knowledge and ability, their control of their learning, their place in school and community and their rights to a voice. Classroom processes and assessment practices have convinced them that they are not capable of achieving (ability). Their classrooms have been characterized by daily struggles over discipline and behavior (control). They have not seen themselves as valued as individuals and learners (place). There has been little opportunity for them to have a say in their learning processes and achievements (voice). This has resulted in their often not gaining classroom access to powerful and contextualized knowledge. All of these issues have clear implications for children's sense of agency and subsequent ability to feel like they can contribute as equal citizens, a central tenet of democracy.

Ideologies and curriculum

Another important dimension of curriculum is the ideology that underpins its design. Schiro (2013) argues that there are four dominant ideologies which shape curriculum practice in the United States, which have equally shaped ideology about curriculum and the potential place of democracy in curriculum in other countries too. These four ideologies are:

1. Scholar academic ideology
2. Social efficiency ideology
3. Learner-centred ideology
4. Social reconstruction ideology.

The *scholar academic ideology* is based on the notion that each culture has accumulated a body of knowledge over the centuries, which is organized into academic subject disciplines, which is needed to take part in contemporary society. The OECD (2006) classified any ECE curriculum that follows this ideology as a “pre-primary approach”, because the content of the curriculum mirrors traditional subject teaching in primary schools. The child is viewed as incomplete in this ideology—a “neophyte” or immature member of the discipline—who is capable of developing intellect, memory, and reasoning, shaped by the discipline (Schiro, 2013). This immature, “blank slate” or “empty vessel” view of the child, drawing on the notions of Aristotle and John Locke (Cleverly and Phillips, 1995), suggests that the role of the school or early childhood setting is to fill the child with predetermined knowledge and skills, a passive model of child development and learning. Learning is thus viewed as a function of teaching: the teacher is a transmitter, and the child is a receiver. De Castro (2012) argues that in such models, children labor in the present for coming into a social existence in the future and are thereby set aside from relevant social interactions and opportunities because they are not yet deemed prepared to take part in them. In a critique of such models, de Castro (2012) argues that the focus is on what children cannot do, rather than what they can do, and the child is constructed as non-adult and therefore irrational, vulnerable, immature, and dependent. In this model, the child is therefore the receiver of pre-existing models of democratic understanding over time and it is unlikely that the child will be involved in democratic decision making until seen to be at an appropriate age and stage for such learning within the curriculum. As Bubikova-Moan et al. (2019) argue, such approaches to curriculum are didactic and focused on explicit outcomes, such as school readiness. In this model, children are unlikely to readily experience or gain understandings of democracy.

The *social efficiency ideology* is based on the writings of Bobbitt (1918), and his book *The Curriculum*, and further developed by Ralph Tyler in 1949 in *Basic Principles of Curriculum and Instruction*, in which both authors declared that educators should learn to use the scientific techniques of production developed by industry to improve the outcomes of education. In this ideology, the school is the equivalent of a factory, and the child is the raw material: an adult is the finished product; the teacher is the factory worker, who runs the machines. A teacher in this model must determine what the finished product needs to be and then determine the most efficient way to achieve that outcome. Bobbitt (1918) proclaimed that the educational “task preceding all others is the determination of ... a scientific technique” of curriculum design (in Schiro 2013, p. 57).

If a democratic citizen was the desired outcome, then teachers would devise curriculum which would enable this learning to happen. Social efficiency educators devote much time to developing objectives in behavioral terms: as observable skills, capabilities for action, activities to be performed—demonstrable things people can do. For example, a behavioral objective related to democracy in early childhood might include social competency: in this case, the ability to take turns during an organized activity. The actions are clearly specified—taking turns in an organized game—and the child’s ability to take turns can be clearly observed and measured during the activity. An efficient curriculum in this ideology is one in which children experience a controlled learning environment, in which content is carefully sequenced and efficiently organized. This is often called a programmed curriculum. For example, the curriculum would be organized so that teachers could plan their teaching programs for incremental success of children becoming democratic. The curriculum developer’s role is that of “behavioral engineer” (Holland, 1960).

The assumptions underpinning this ideology involve the assumption that learning is in response to direct stimuli and that it’s a teacher’s role to organize stimuli and provide increasingly more complex organized activities to promote learning, which will stimulate children to practice the desired behaviors, which will result in the desired learning outcome. This approach to curriculum development supports the teaching method of planning for observable and directly measurable objectives. In many ways the Early Years Foundation Stage Profile (Standards and Testing Agency, 2016) with its 17 specified learning goals and achievement standards parallels this notion. The High/Scope® curriculum, although focused on children being active learners, is another example, as the curriculum includes 58 key experiences in child development for the preschool years and a wide range of practical strategies for promoting these key experiences (OECD, 2004). Goal 3 Initiative and Social Relations (to make plans, decisions, solve problems encountered in play, express feelings, be sensitive to others) is related to loosely related to notions of being a good citizen, but the notion of being agentic is missing from this and other goals. Education is therefore seen as a shaping process in this ideology, preparing children to create a better society and this notion is consistent with the definitions of democracy proposed by Cohen (1971), argued earlier. Children are seen as potential members of the adult society and as workers capable of putting energy into the education endeavor. The teacher is the “manager of the conditions of learning” (Gagne, 1970, p. 324) and teachers plan curriculum for average students, with adjustments for some students. Success in this curriculum model is defined as achievement of the learning objectives, which could include displaying democratic behaviors.

Learner-centred ideology is based on the concept of an ideal school, or what Dewey (1916) called “the school of tomorrow”. Current models which typify this ideology include Montessori preschools and Reggio Emilia schools (OECD, 2004). In learner-centred ideology, the needs of the individual child dominate, rather than the needs of teachers, school subjects, school

administrators or community groups. Within this ideology, a curriculum is focused on children having hands-on experiences and therefore involves children being actively involved in democratic practices themselves (MacNaughton, 2007; Myskiw, 2019). Activity is a key term—physical, social, verbal, and emotional (Schiro, 2013)—and takes place both inside and outside the classroom. The history of these ideas can be seen in the ideas of several key thinkers: Comenius (1592–1670), who argued that learning moves from concrete experience to abstract thought; Jean-Jacques Rousseau (1712–78), who believed that the purpose of education was to nurture children’s innate goodness and that learning should result from direct experiences; Johann Heinrich Pestalozzi (1746–1827), who argued that children should be free to pursue their own interests and advocated for the freedom of the “whole child”; and Friedrich Froebel (1782–1852), who invented the kindergarten, which was based on the education of children’s senses and the use of “gifts” and “occupations” that allowed children to perceive the order and beauty of nature as a result of interacting with it. Also associated with this ideology are G. Stanley Hall (1844–1924), the founder of the child study movement, in addition to John Dewey (1859–1952), who argued that “children learn by doing”.

A curriculum based on these ideas uses an integrated approach, based on principles of educating of the “whole child”, which integrates children’s home and school lives. It uses interdisciplinary approaches to academic disciplines and assumes that children will actively integrate their own knowledge in their own way and that there are multiple pathways to learning. The learner-centred ideology is humanist in orientation—the fundamental principles are about human growth, the potential for self-actualization, and the need for personal autonomy (Cleverly and Phillips, 1995). Learning is seen to occur through the child’s interaction with the environment and the dominant learning theory used is constructivism, often using Jean Piaget’s theory (see Bredekamp, 1987). Piaget’s (1936) theory proposed that children are active learners, and their interaction with the physical world provides the main constraints on and contributions to the development of their intelligence: children learn and construct meaning as they act upon objects in space and time.

More recently, social constructivism, based on Lev Vygotsky’s (1978) theories, has also been expressed within this ideology (see Copple and Bredekamp, 2009). Project approaches to learning are typical in this ideology—teachers help children scope and sequence learning and enable children to move from personal, concrete, and physical learning experiences to abstract, verbal and intellectual understandings (Schiro, 2013). In this ideology the teacher is not a transmitter, but carefully observes the children and sets up environments to support learning, including notions of democracy. The teacher may also intervene between the child and the environment to assist learning. Teachers working within this learner-centred ideology will develop curriculum in ways which integrate knowledge with children’s growing sense of themselves as democratic members of their society. Te Whāriki (Ministry of Education, 1996, 2017) and the Early Years Learning Framework (DEEWR, 2009) are good examples of this type of curriculum, which promotes the notion of preparing children to become good citizens of the early childhood community and wider society.

The *social reconstruction ideology* is premised on the idea that our society is threatened by many problems and that education is the cure. Giroux’s (2006) writing typifies this approach to curriculum:

Educators need to assume the role of leaders in the struggle for social and economic justice ... Educators must connect what they teach and write to the dynamics of public life ... and concern for ... democracy (p. 9).

According to Giroux, democracy is grounded in the notion of the citizen as an active and critical agent supporting principles of “sociality and community” (1989, p. 34). Giroux’s definition of democracy suggests he is a proponent of “idealist” democratic theory, which is concerned with both specific processes of governance, but also with producing certain types of public-spirited citizens (Arthur and Sawyer, 2009). From this standpoint on democracy itself, Giroux then argues that the aim of education in a democracy is equity and social justice, creating relations with communities and improving the “quality of public life” (1989, p. 19). Education for Giroux is therefore both a process and a product in itself: education is a moral, civic, public, and social enterprise aimed at creating the kind of citizen who might fit well into the idealist conception of democracy. One key strategy is linking students’ in-school experiences to those of their wider communities—in Giroux’s view, thus enabling a “voice” (1989, p. 200) and a sense of critical agency; he argues that schools are best understood as a locus of citizenship (Giroux, 1989, p. 201). Certain pedagogies permit agency to manifest itself by allowing students to use their own social and cultural capital (Arthur and Sawyer, 2009); thus, enabling students to feel like they belong, they are active agents in their own learning, able to make choices and co-construct meanings and identities (Dahlberg et al., 2007). These notions are increasingly reflected in curriculum for compulsory schooling and early childhood education.

Critical pedagogy, which the philosophy of education promoted by critical theorists such as Giroux (1989), Freire (1972), Apple (1979, 1982), and Foucault (1977) is underpinned by the belief that schools and curriculum are designed to legitimate some ideas and suppress others. Critical pedagogy is thus designed to disrupt and undermine the conventional forms of understanding, which serve to reproduce undemocratic, racist, sexist and unequal social relations. Implicit in this ideology are ideas of student-centredness, student empowerment and emancipatory citizenship as means of subverting the traditional social reproduction of schools, power relationships, hidden curriculum and inequalities produced by curriculum.

In relation to young children in this world view, ECE settings are often children’s first experiences with the wider community and are increasingly being recognized as a place where they can experience democracy and “citizenship” (MacNaughton, 2007). MacNaughton has demonstrated that young children have “powerful, insightful, valid and valuable” views on a range of issues relevant

to their lives (MacNaughton, 2007, p. 460). Accordingly, children's interests in issues such as the environment and social justice are starting to be included in curricula (Edwards and Cutter McKenzie, 2011) and in research about how children learn to become agentic citizens through their engagement in community projects, such as Rameka's research in New Zealand about culturally sustainable practices in ECE settings (Paul-Burke and Rameka, 2015). Teaching and learning in this ideology in ECE are based on the physical and social context and what the issues are in their community.

The principles of teaching children how to be good, democratic citizens is seen most clearly in the Nordic countries (Jensen, 2009). For instance, in the Swedish early childhood curriculum children are not just exposed to some of these big ideas, such as human rights; they are actively engaged as learners with issues—for example, one of the curriculum goals for children is “an understanding of democratic principles and the ability to cooperate and make decisions in accordance with them” (Swedish National Agency for Education, 2019, p. 17). Learning is based on experiences that intellectually and emotionally involve the children. Group discussion is a key instructional method, and values, feelings, injustices, alternatives and solutions are explored. The teacher is seen as a colleague, who has experiences to share with the children, rather than as an expert. Centers are thus seen as institutions of change, in which children are prepared to change society for the better. Children are not seen as children, but as potential contributing members of society who can aid reconstruction (Schiro, 2013); clearly demonstrating notions of social reconstruction ideology. Sweden's national curriculum is aimed to make day-care “take care of and support children in developing their ability to feel responsibility and social readiness to act in order to establish solidarity and tolerance” (Swedish National Agency for Education, 2006, p. 3). Furthermore, the objective is to “encourage and strengthen child's sympathy and empathy for other the situation of others” (Swedish National Agency for Education, 2006, p. 3) and “no child should be subjected to discrimination at pre-school based on gender, ethnic belonging, religion or perception of other belief, or sexual orientation” (pp. 3–4). An important point is that ECE sets the grounds for lifelong learning and that ECE must present possibilities for children's play, concentration and interplay between child and surroundings in order to develop children's societal understanding and understanding for mutual democratic values. Issues of social inequality and differences between children is addressed implicitly by writing that no child should be discriminated against.

Einarsdóttir et al. (2015) argue that a high priority is given to the values of social inclusion within the Nordic model, in which every citizen should have equal opportunities to participate in society (Kristjánsson, 2006). The Nordic ideal of child-centeredness specifically focusses on democracy as an outcome of participation in ECE, as it includes key notions of the naturalness of childhood, equality and egalitarianism, democracy, freedom, emancipation, warm and cooperative social relationships, and solidarity with Nordicness (Wagner and Einarsdóttir, 2008; Wagner, 2006). Nordic countries often also oppose introducing standards for learning too early in children's lives because of the risk that such standards may limit the children's free development (Jensen, 2009). Notions of school readiness are similarly opposed, as it could clash with a Nordic value of the good childhood, which means that ECE have to practice democracy in which children have to be active participants and have a voice in their own everyday life (Committee of the Rights of the Child 1989). For example, in Finland, the national curriculum revolves around cognitive, ethical, social, religious and aesthetic objectives (Ministry of Social Affairs and Health Finland, 2004, p. 24) and the teacher has to work toward these objectives, rather than fixed learning standards. Early childhood is seen as part of the overall objective of lifelong learning, as it is in Sweden. In this model, ECE is part of a seamless whole, with special emphasis on treating children as equals. “Early childhood education in Finland is based on a view of the child as a human being whose growth, development and learning happens in formal and informal ways in different environments” (Niikko, 2006, p. 142).

As this analysis suggests, it is possible to build principles and pedagogies for democracy into early childhood curricula, as the Nordic governments has done, but this reflects the cultural values of the society, as the OECD (2019) proposed. To ensure that children learn how to be democratic, the principle needs to be embedded in the learning goals of the curriculum and then enacted by teachers in the ways in which they involve children in the decision making in each early childhood setting. As Myskw (2019) demonstrates, this can be done within the Australian early childhood curriculum context, but it requires teachers to set up processes for engagement with children about how they want the center to run.

As this section has explored, it is possible to think about curriculum and democracy for young children, but this discussion can't be completed without examining notions of children's rights in relation to the delivery of curriculum. These issues will be explored next.

Children's rights: part of democratic practice?

One of the most interesting aspects of the debates around children and curriculum concerns the United Nations Convention on the Rights of the Child (UNCROC) (United Nations, 1989). De Castro (2012) argues that the situation of children changed in the late decades of the twentieth century once they became the objects of legislation of specific rights via the UNCROC agreement. The UNCROC agreement was supported by all world state nations, except the United States and Somalia. From this followed national statutes and bills which could secure and enhance the international legislation, creating a new subject position for children as “subjects of rights”. It is important to note that the granting of children's rights have not been the result of children's own dispute over their social conditions and therefore were not sustained by children's actions to assert their rights to certain social conditions. As de Castro (2012) points out, adults spoke in children's “best interests” and therefore it was unclear what relationships and acts of oppression were creating challenges for children. The moral dignity of children came hand in hand with the legal need to be protected, cared for, and educated by adults. The upgrading of children's positions to that of upholders of rights has enhanced their

visibility as objects of public policy, rather than as actors with agency in their own society as Giroux (1989) proposed. Paradoxably, although the UNCROC agreement makes children more visible to the public and a matter for public policy and investment, it equally positions children as vulnerable, lacking capacity and in need of adult protection. The right to participate, according to the agreement should only be “given” to children on the condition that they demonstrate beforehand their cognitive and linguistic competence to participate (De Castro, 2012). This position on children’s competence is so vague, that it engenders notions of protecting children, rather than seeing them as holding legitimate opinions on what their lives should be like.

De Castro (2012) argues that the scientific study of children in different disciplinary fields has largely treated children and politics as two distinct and unrelated domains. Furthermore, when children have been considered in relation to politics, she argues that the discussion avoids any consideration of children as political actors with agency, as Giroux (1989) argued. Instead, “child politics” refers to the gradual appearance of children as objects of public policies, culminating in the ratification of UNCROC by almost all nations. Currently, 196 countries are party to it, including every member of the United Nations, except the United States. De Castro concludes that because of the different political regimes, different levels of economic development and different interests by nations in international conventions and social issues, the ways this convention is enacted by countries varies considerably. It has also meant that the focus is broadly on protection of children and their rights, rather than a focus on children’s significance and contribution to political life, democracy or indeed to society. This outcome means that children are perceived as in need of protection, rather than also being actors in their own lives.

Taylor (2009) has similarly argued that children are viewed as an object of adults’ concerns, as projects or persons in the making, and as objects of society’s cost/benefit calculation of how much investment they should receive. In either perspective, as Taylor argues, children not perceived as agentic or a participating member of a democracy; they are simply an adult concern. Many countries enactment of the UN Convention endorse this approach, suggesting that the focus is on ensuring children simply have access to health and education, rather than democratic opportunities to offer opinions on their lived experiences. De Castro (2012) argues that this positioning of children as objects needing attention by adults needs re-evaluation. Viewed as “rights holders” a more participative role for children in society should be possible. There is a taken for granted aspect to children as subjects in need of protection that is clearly challenged in some national curriculum, particularly in Nordic countries (e.g. Einarsdottir, 2008; Jensen, 2009), and this is an issue that needs re-evaluation in many countries which are signatory to the UNCROC agreement. Although designed to ensure that children have rights to health and to education, the right for children to have a say in their own lives is a matter which is less clear in most curriculum (Jensen, 2009; Einarsdottir and Wagner, 2006). The reference to the United Nations Convention on the Rights of the Child (UNCROC) in the revised New Zealand early childhood curriculum, *Te Whāriki* (Ministry of Education, 2017) also signals the obligation on teachers to support children’s rights to health and education. The curriculum states: “Kaiaako (educators) work to uphold and protect children’s rights, interests, and points of view from the earliest ages” (p. 61). Notably, although New Zealand was signatory to the UNCROC agreement in 1993, there was no reference to it in the 1996 version of the curriculum. This change suggests a greater consciousness of the need to recognize that children can and should have a “voice” (Giroux, 1989) in early childhood settings.

Grindheim (2017) argues that the move away from an adult-centred view of citizenship allows for recognizing different forms of participation in both formal and informal settings. She argues that research has delineated how an adult-centred understanding of where and how democratic participation is to be exercised may not accord with how children participate, inhabit, negotiate, and challenge the given conditions for participation. She proposes that educators need to explore the notion of “citizenship as practice” (Lister, 2008), which is understood as the way children exercise their rights within ECE settings and is conceptualized as different ways of participating within their given context. Grindheim (2017) further argues that play is understood as activities that frame ways of participating, which are culturally framed and have included limited opportunities for freedom. Nevertheless, children as “child-citizens” do challenge, change and interrupt the given conditions, using a variety of participation forms. She suggests that through play, children can learn about citizenship and democratic participation.

Sousa and Oxley (2019) found that democracy is elastic, flexible and distinctive within specific educational contexts, rather than a self-evident and universal consensual truth. They argue democracy needs critical discussion and analysis in order to “survive” within the contexts of ECE practice; it cannot be taken for granted. Each of the three ECE settings in Portugal that Sousa and Oxley examined (one public, one private, one religious not for profit) had a distinctive range of representations of democracy, with foci varying from the individual to the group. Rather than one version of democracy, Sousa and Oxley found that democracy was represented differently in each of the three ECE settings, presenting new forms of active and critical democratic citizenship with the potential to contribute to the reduction of social inequality.

Myskiw (2019), who designed her early childhood curriculum in Australia on democratic principles to build children’s sense of agency, argues that a key feature is making sure that children’s voices can be heard. Although she acknowledges that the United Nations Convention on the Rights of the Child (United Nations, 1989) states that “the views of the child ... (shall be) given due weight in accordance with the age and maturity of the child” (article 12, S1), she argues that the question of “age and maturity” for early childhood practitioners is more about how a child’s voice should be heard, not whether they shall be heard. As she states, children’s voices and views about matters affecting them, no matter how large (consent, privacy) or small (the size of vegetables in their meals) should be a considered and supported democratic and ethical process. As she states:

It is radical thinking to set up a forum for debate that promotes the discussion of rights; it is even more radical to respect, listen to, and enact the outcome of the discussion. That’s when we enter a real dialogue and practice of enacting children’s rights in early childhood settings. Sometimes the

meetings go for a long time and sometimes they fizzle out after five minutes, but it is important to honour the process and turn up every time, because the children's image of us as leaders is now changing too" (p. 16).

Within this setting a "Children's Council" was established in which children and teachers negotiated the matters that concerned them. Myskiw (2019, p. 16) states that the following features of democracy are crucial to the success of such a venture:

- Strong relationships with children embedded in to practice
- Whole community approach
- Building a foundation of rights
- Creating a movement: lobbying and children as active citizens
- Image of the child
- Pedagogy of listening
- Rights education

Fleer (2003) similarly proposed that the way forward for ECE is to build a new "community of practice", using Wenger's (1998) terminology, in which teachers use a range of cultural tools to work with children and their families to build on the social and cultural strengths that they bring to their learning. One such example is the Philosophy for Children (P4C) movement, which aims to give voice to childhood thinking through philosophical practice. The curriculum is based on the construction of Communities of Inquiry (CoI), which promote reasoning and argumentative skills, foster creative imagination and develop caring dispositions (Di Masi and Santi, 2016). Founded by Professor Matthew Lipman in the 1970s in New York, P4C comprises a curriculum that emphasizes the formative dimension of philosophy with a CoI, which promotes "an approach that puts the child at the center and emphasizes learning by discovery and experiment, and the construction of knowledge" (Vansieleghem, 2005, p. 19). It is a general aim of Philosophy for Children to include the voices of every member of the community on the grounds that the more voices are heard, the greater will be the possibilities of reaching a general and appropriately representative consensus. Philosophy for Children is based on the proposition that critical thinking and dialogue, based on Bakhtin's (1981) notions of "voice" and Wenger's (1998) notions of "communities of practice" are the necessary conditions for emancipating children from determination and for transforming them into democratic, free citizens (Vansieleghem, 2005, p. 20); dialogues based on child participation in shared reasoning and argument evaluation critical autonomous thinking and prevents indoctrination according to this curriculum approach. Using a dialogic approach is argued to create the opportunities for children to become democratic citizens.

Summary and conclusions

An exploration of the concepts of curriculum and democracy have been explored in relation to the types of curriculum that have been used over time to support young children's learning. Using Scott's (2008) useful definitions of curriculum and Schiro's (2013) explanations of the key ideologies underpinning approaches to curriculum, this chapter has examined the different types of curriculum and whether they are fit for purpose for supporting children to become democratic citizens of a society. As this exploration showed, the only curriculum that are specifically designed to support children to develop a sense of agency within a democracy are based on social efficiency ideologies, in which the goals for children to develop their own "voice" and to actively participate in democratic processes are clearly outlined. These types of goals are more common in the Nordic countries (Jensen, 2009) but are also emerging in revisions of other curricula, such as in New Zealand (e.g. Ministry of Education, 2017). This chapter has also explored the tensions between the positioning of children in the United Nations Conventions on the Rights of the Child (1989) and curriculum, as children are typically positioned as in need of protection by more learned others, rather than being agentic in their own right. Arguably, many nations need to reflect more fully on what children's rights to health and education mean in relation to the early childhood curriculum. There is clearly a need for teachers, providers of initial teacher education and policy makers to reflect more fully on what it means to support children to become members of a democracy.

The school curriculum communicates what we choose to remember about our past, what we believe about the present, what we hope for the future.
[Pinar \(2004, p. 20\).](#)

"Queer," to me, refers to a politics that values the ways in which meanings and institutions can be at loose ends with each other, crossing all kinds of boundaries rather than reinforcing them. What if the most productive junctures weren't the ones where everything means the same thing?
[Sedgwick \(2011, p. 200\).](#)

The curriculum communicates many things about our past, present, and future. If LGBTQ+ people and issues are not recognized in the curriculum, students are left with an inaccurate understanding of their community's past, present, and future. Recognition in the curriculum signifies the individuals, groups, social issues, and events that are of value to the community. Conversely, a lack of recognition within the curriculum signifies what individuals, groups, social issues, and events are of little value to the community or worse. When a dominant group is presented as the norm, this presents a picture of a standard in which all other groups are judged. It is as if this dominant understanding is fully human, and marginalized groups as lacking or less than human. Throughout history, the erasure and mistreatment of LGBTQ+ individuals have illustrated how dominant groups treat them as less valuable or less than human. Dehumanization is a tool used by dominant groups to justify mistreatment and violence against LGBTQ+ individuals and groups. This highlights inequitable power relations because a lack of recognition is framed by dominant groups, so absences and misrepresentations bolster inequalities. Because of omission from the curriculum, the marginalization of LGBTQ+ individuals and issues continues, and dominant sexualities and gender identities are reinforced.

As matters of equity, democracy, and social justice, inclusion is a necessity, and student inquiry into social inequalities needs to be a central theme that guides the curriculum.

This chapter presents a summary of my research and ways to conceptualize, design, and implement LGBTQ+-inclusive curriculum within the context of critical democratic education. The curriculum sends powerful messages to students and society about what experiences, knowledge, and identities are valued by communities. I first examine curriculum as an indicator of power relations between individuals and groups within society. Second, I present a heuristic for understanding how to increase LGBTQ+ inclusion through situated knowledge. Next, I connect the first and second parts of the chapter through the concept of critical education for democracy. The legitimacy of democratic communities relies upon the recognition of the voices and perspectives of individuals and groups within the community. This applies to LGBTQ+-inclusive curriculum in democratic communities as perspectives in the curriculum more accurately reflect the range of perspectives within a community.

With the exception of a few states ([GLSEN, 2019](#)), LGBTQ+ individuals, histories, and issues have not been recognized in the curriculum throughout the United States. State curriculum standards are exclusionary ([Camicia and Zhu, 2019](#)) and driven by anti-gay curriculum laws ([Rosky, 2017](#)). This lack of recognition is harmful to LGBTQ+ students who do not see themselves as represented or valued in the curriculum ([Burdge et al., 2012, 2013](#); [Kosciw et al., 2012, 2014](#); [Mayo, 2014](#); [Snapp et al., 2015](#)).

A lack of LGBTQ+ recognition and inclusion in the curriculum also has implications for how students learn about democratic governance ([Camicia, 2016](#)). Since democratic governance relies upon the voices and perspectives of the governed, a lack of recognition and inclusion of LGBTQ+ individuals and issues sends messages to students and the community about the relationship between democracy and inclusion. Students might believe that they are participating in democratic communities while the exclusion of LGBTQ+ individuals and issues undermines democratic governance. In other words, students are presented with competing messages in the curriculum. One message extols the importance of democracy while another message suppresses the inclusion of LGBTQ+ individuals in the curriculum. A democracy with limited inclusion is a weak form of democracy ([Camicia, 2009](#)). This chapter examines the relationships between curriculum, LGBTQ+ inclusion, and democratic communities.

Power relations, curriculum, and recognition

The curriculum is not designed and enacted in a decontextualized vacuum. Instead, the curriculum reflects the interests of dominant groups and norms (Apple, 2018). As such, the curriculum often fails to reflect the interests of marginalized and minoritized groups (Au, 2012; Au et al., 2016). Numerous studies have illustrated how textbooks (Brown and Brown, 2010; Camicia, 2007) and state curriculum standards (Anderson and Metzger, 2011; Busey and Walker, 2017; Eargle, 2016; Journell, 2009; Shear et al., 2015) do not recognize or misrecognize the histories of marginalized groups. Curriculum standards and instructional materials reflect an official stance of the state, so the messages that they send function to reify existing power relations within society. Because LGBTQ+ individuals and issues have been marginalized by society, the curriculum usually reflects this marginalization. In this way, the curriculum is a reflection of inequitable power relations.

With exception of a few states, LGBTQ+ individuals have been missing from the history curriculum across the United States. At the time of their data collection in 2016, Camicia and Zhu (2019) found that only seven states mentioned the terms LGBTQ in their K-12 social studies curriculum standards, and of the seven, only California included LGBTQ individuals and issues in any substantial way. Because social studies education in public schools comprises subject areas such as civics, history, economics, and geography, the absences or misrepresentations of LGBTQ+ individuals and issues in the subject areas are especially harmful to LGBTQ+ individuals and the community. The absences in state standards are an indication that LGBTQ+ curriculum is a null curriculum (Eisner, 2002) because there is a substantial absence of recognition. In addition, when LGBTQ+ individuals are recognized in the curriculum, the curriculum is often overrepresented by white, gay men. Bickford (2017, 2018) found that LGBTQ-based literature for elementary and intermediate level students followed this pattern, and transgender individuals were rarely recognized. This lack of recognition reflects dominant patterns of inequitable power relations within communities. The marginalization of LGBTQ+ individuals in society does not diminish when students enter schools. The marginalization is usually mirrored in the curriculum. As matters of social justice and human rights, the curriculum needs to include LGBTQ+ individuals and challenge inequalities that are perpetuated through the curriculum.

LGBTQ+ inclusive curriculum

Within the context of LGBTQ+ exclusion in the curriculum, educators can design and implement curriculum and instruction that is inclusive. This involves teacher education (Lilienthal et al., 2018; Murray, 2014), supportive administration (Hernandez and Fraynd, 2014; Mayo, 2014), and inclusive curriculum (e.g., Helmer, 2016; Logan et al., 2016; Moorhead and Jimenez, 2021; Sadowski, 2016; Souto-Manning and Lanza, 2019). One of the main strategies for increasing inclusion can be guided by queer theorizing where, as Sedgwick (2011) writes, we create opportunities for “crossing all kinds of boundaries rather than reinforcing them” (p. 200). In the area of curriculum, this means creating opportunities for students to question norms that reify the oppressive boundaries related to genders and sexualities.

In addition to the powerful messages about sexuality and gender that students receive from dominant groups in society, schools are sites where dominant norms are reinforced by the curriculum. Related to gender, pervasive binary constructions of gender are ubiquitous in the curriculum. This is often exacerbated by school activities that group students into categories of boys and girls, social events where binary gender and gender stereotypes are policed, and instructional materials that perpetuate fixed qualities for gender categories.

For the curriculum to be more inclusive, it needs to challenge exclusionary language by expanding perspectives and challenging gender stereotypes and binary gender. For example, rather than referring to boys and girls while communicating with students, educators can use gender-neutral terms. Souto-Manning and Lanza (2019) provide illustrations from an elementary school where students problematize the labels of boys and girls bathrooms and deconstruct gender stereotypes through the use of trade books. These books help students identify the types of labels that categorize people as a way to police gender norms. Students can also learn about historical and contemporary figures who do not fit within binary gender construction or identify with a gender other than the one that they were assigned at birth. In these ways, the curriculum expands inclusion by opening possibilities for gender expressions.

For the curriculum to be more inclusive of sexualities, it can provide spaces for students to challenge heteronormativity. Dominant norms of heterosexuality serve to exclude consideration and recognition of diverse sexualities. Helmer (2016) describes a high school English classroom where students deconstruct literary texts to identify hidden assumptions and norms related to sexuality. Helmer writes that the teacher “directly challenged her students’ heteronormative reader expectations and a ‘straight’ reading of the text” (p. 40). By challenging heteronormativity in interpretations of literature, the curriculum can increase inclusion. Students can also challenge the stereotypes of minoritized sexualities by identifying stereotypes and providing counternarratives that dismantle the stereotypes. I discuss counternarratives later in this chapter.

Given the proliferation of media that students experience, another area for increasing inclusion is in student deconstruction of media images and texts. Students can ask: What stereotypes of genders and sexualities do the texts communicate? What assumptions underly the messages in media such as commercials? When LGBTQ+ characters are included, what roles do they play, and how are they portrayed? These questions can also be applied to instructional materials across the curriculum in areas such as history, language arts, mathematics, art, and science. Rather than being restricted to literature, students can learn about people from multiple disciplines whose sexualities or genders have been erased in the curriculum.

Students also need to understand that there are multiple forms of oppression related to social inequalities. LGBTQ+ individuals have overlapping identities that position them within society (Moorhead and Jimenez, 2021). Oppressive ideologies and discourses of racism, sexism, classism, ableism, and exclusionary nationalism overlap the identities of LGBTQ+ individuals. By helping students understand these overlapping forms of oppression, the curriculum can increase inclusion.

In the next section, I present ways for students to identify and address exclusion as a way to increase inclusion and make their communities more democratic and socially just. The curriculum is an expression of how we understand the past and present, as well as what we hope for the future (Pinar, 2004). I turn to democratic theory as a way to envision the types of communities that we offer as choices for students. Is it a community based upon democratic inclusion of LGBTQ+ individuals or a community based upon authoritarianism and exclusion?

Critical democratic education and LGBTQ+ inclusive curriculum

One of the ways to increase our understanding of LGBTQ+ inclusion in the curriculum is to conceptualize inclusion as it relates to democracy (Camici, 2016). This provides a strong rationale for increasing the perspectives of LGBTQ+ individuals and social issues. Although an inclusive curriculum is good for the mental, physical, and academic health of LGBTQ+ students (Kosciw et al., 2020), all students and communities are strengthened by increased recognition. This is based upon the assumption that communities value democratic rather than authoritarian governance. If we value democratic governance, then the legitimacy of the curriculum relies upon the inclusion of all who are subject to the curriculum. This means that during student inquiry and discussion, the perspectives of LGBTQ+ individuals are included in the curriculum. This necessarily involves an understanding of how power functions to privilege some voices while marginalizing other voices because LGBTQ+ individuals have been and continue to be silenced and worse within society. Young's (2002) elements of inclusion within democracies provide guidelines that transfer to increasing LGBTQ+ inclusion in the curriculum. These elements are termed greeting, rhetoric, and narrative.

Greeting

Young (2002) described greeting as an ethical agreement to recognize people for whom they are rather than placing them in exclusionary categories. As applied to curriculum, this means agreeing to search for meaning and being open to changing perspectives once another perspective is presented. Under greeting, there is an understanding that we experience the world differently, and those experiences create diverse ways of understanding social issues. A commitment to greeting is a commitment to democratic governance because the views of community members are valued when considering issues of importance to the community. Young wrote:

Greeting, which I shall also call public acknowledgment, names communicative political gestures through which those who have conflicts aim to solve problems, *recognize* others as included in the discussion, especially those with whom they differ in opinion, interest, or social locations. By such Sayings [sic] discussion participants acknowledge that the others they address are part of the process, and that we who address them must be accountable to them, as they to us. (p. 61, emphasis in original)

This recognition is central to LGBTQ+-inclusive curriculum because LGBTQ+ individuals have been and continue to be rendered unrecognizable by dominant groups who make heteronormative, gender, and binary assumptions. As has already been described above, the curriculum can include historical examples of this lack of recognition through student examination of LGBTQ+ individuals and issues that have not been part of the curriculum across subject areas.

In the curriculum, greeting and recognition can increase among students through activities such as identity maps (Moorhead and Jimenez, 2021) and writing about labels and identities (Souto-Manning and Lanza, 2019). By exploring and sharing about identities and lived experiences, students can develop an understanding that some of the dominant categories often render the perspectives and identities of LGBTQ+ individuals unrecognizable. By presenting historical and contemporary examples of heteronormative and gender assumptions, the curriculum can open student conversations about an ethical agreement to recognize each other in the diverse ways that we understand ourselves and our identities. This is a vital component of education for democracy because recognition of diverse sexualities and gender identities can expand perspectives on social issues. A commitment to greeting is a commitment to including the perspectives of those subject to decisions in the decision-making process. As such, LGBTQ+ inclusion is an important component of a healthy democratic community.

Rhetoric and discourse

Young (2002) presented rhetoric as a second element for increasing inclusion in democracy. When discussing social issues in public spaces, norms of conversation and discourses influence what can and can't be said. This relates to the experiences of LGBTQ+ individuals because there is a long history of banning conversations about sexuality and gender. Young wrote;

The ideal of disembodied and disembedded reason that it presupposes is a fiction. What such privileging takes to be neutral, universal, and dispassionate expression actually carries the rhetorical nuances of particular situated social positions and relations, which social conventions do now mark as rhetorical and particular in the same way that they notice others. (p. 63)

The element of rhetoric can focus student inquiry and conversation on the ways that certain ways of talking about social issues are accepted by dominant groups. These groups define the boundaries of what is acceptable to talk about in public. Because LGBTQ+ issues have been regarded by many as inappropriate to discuss in schools (Rosky, 2017), it is important for students to examine the reasons for these prohibitions. Students can examine these *anti-LGBTQ+* laws and policies as texts for their classroom inquiry and discussion. They can ask, “Whose interests do these laws and policies serve?”

While Young (2002) did not explicitly refer to discourse, the connection can be helpful in using concepts of discourse analysis to help students better understand democratic inclusion and rhetoric. Hall (2001) wrote that discourse:

Defines and produces the objects of our knowledge. It governs the way that a topic can be meaningfully talked about and reasoned about. It also influences how ideas are put into practice and used to regulate the conduct of others. Just as a discourse ‘rules in’ certain ways of talking about a topic, defining an acceptable and intelligible way to talk, write, or conduct oneself, so also, by definition, it ‘rules out’, limits and restricts other ways of talking, of conducting ourselves in relation to the topic or constructing knowledge about it. (p. 72)

Dominant discourses in society and schools shape what can and can’t be said about sexualities and genders. This can have a profound impact on the ways that students can understand their communities, LGBTQ+ individuals, and LGBTQ+ issues. The curriculum can be more inclusive by examining the ways that discourses of transphobia, homophobia, and heteronormativity have influenced the degree of inclusion that LGBTQ+ individuals experience in and out of schools. While identifying these discourses, student inquiry can examine the ways that inequitable power relations perpetuate these discourses in the interest of dominant groups. With greeting and rhetoric, students can start understanding how to increase the democratic inclusion of LGBTQ+ individuals and foster democratic discourses.

Narrative and counternarrative

The third element of Young’s (2002) model of making democratic spaces more inclusive involves valuing the lived experiences of individuals and groups. When shared in classroom inquiry and discussion, these experiences can provide the text and examples that students need to understand how knowledge is situated and constrained by inequitable power relations. Young described the role that the element of narrative can play in the curriculum:

By adopting narrative as a pedagogical tool, teachers and students open up possibilities to make links between their experiences and those of strangers in distant places, including links between these strangers’ struggles for justice and their own. Narratives used in this way can be used to advance justice and human rights through education. (p. 49)

By opening the curriculum to a variety of experiences, students can better understand the experiences of LGBTQ+ individuals. These experiences often communicate a counternarrative to the narratives of dominant social groups. Because the curriculum has acted historically to bolster dominant narratives, the experiences of LGBTQ+ people have been excluded from the curriculum. Students can examine how historical narratives from a variety of LGBTQ+ individuals and groups were subject to heteronormative, homophobic, and transphobic discourses (e.g., Bronski, 2019; Stern, 2009). Educators and students can refer to resources such as GLSEN (2021), Lambda Literary (2021), Learning for Justice (2021), and Social Justice Books (2021) to help them build counternarratives and a more accurate portrayal of history and social issues. Counternarratives that challenge oppressive discourses can increase LGBTQ+ inclusion in the curriculum through building the influence of democratic discourses.

In addition to examining the counternarratives of LGBTQ+ individuals in history, students can develop their personal narratives in ways that situate their experiences in larger societal patterns of exclusion and inclusion. Methods of autoethnography can be used by students, educators, and community members to increase LGBTQ+ inclusion in the curriculum. Adams et al. (2017) described this method:

Autoethnography is a research method that uses personal experience (“auto”) to describe and interpret (“graphy”) cultural texts, experiences, beliefs, and practices (“ethno”). Autoethnographers believe that personal experience is infused with political/cultural norms and expectations, and they engage in rigorous self-reflection—typically referred to as “reflexivity”—in order to identify and interrogate the intersections between the self and social life.

This increased awareness of connections between personal experiences and larger political/cultural norms can be accomplished in conjunction with Young’s (2002) elements of greeting and rhetoric. By connecting their narratives and experiences with larger discourses in society, students can work toward a better understanding of LGBTQ+ individuals, experiences, and events. There are multiple ways for students to express their narratives. For example, students can create collages, poems, videos, and essays. These provide the material for them to develop their autoethnographies and understand the multiple narratives and situated knowledge within their classroom. In this way, greeting, rhetoric, and narrative are conceptually and pragmatically linked in ways that can increase LGBTQ+ inclusion in the curriculum.

Conclusion

The marginalization and exclusion of LGBTQ+ individuals, issues, and events from the curriculum is pervasive, as evidenced in curriculum standards and instructional materials. As a reflection of the larger society, the curriculum has reflected the interest of dominant groups while diminishing the recognition of marginalized and minoritized groups. This has had devastating consequences for the physical, mental, and academic health of LGBTQ+ students. The exclusion and marginalization of LGBTQ+ individuals and issues have also functioned to undermine the legitimacy and quality of democracy because democratic governance relies upon the voices and perspectives of the governed in decision-making. This makes inclusion in the curriculum a matter of social justice in many ways. The lessons learned from inclusion can be used to create more democratic communities that work against authoritarianism, whether in the form of governance or in the curriculum.

This chapter has presented ways to increase inclusion by designing and implementing a curriculum that challenges dominant narratives and discourses of transphobia, heteronormativity, and homophobia. Critical education for democracy is a way to increase LGBTQ+ inclusion and work against the social injustices that marginalize LGBTQ+ students (Camicia, 2016; Camicia and Knowles, 2021). This focuses upon the themes building ethical commitments of recognizing each other in our differences and using tools of discourse analysis and counternarrative to express these differences. Student inquiry and discussion can place the context of inequitable power relations as a central consideration for how some voices are valued more than other voices. By interpreting the ways that power functions to exclude LGBTQ+ individuals and issues, students can work to dismantle anti-democratic discourses in the service of building democratic discourses. While students learn about these discourses, they can begin to make choices about the types of communities that they want to build and maintain. Are they communities that are exclusionary or inclusionary? Are they democratic or anti-democratic? These choices indicate their approach to equity and social justice.

Introduction: universal design for learning

Curriculum is related to inclusive education in two ways. The first intersection between inclusive education and curriculum is in relation to its content. Particular topics, how children are asked to engage with those topics, and the degree to which discriminatory messages are present may all impact the degree to which children feel they belong in school. The second intersection of curriculum and inclusive education relates to access to the curriculum for children with diverse abilities and preferences. No matter what content is presented to students, if it is inaccessible there will be barriers to learning.

This article focuses on the second intersection of curriculum and inclusive education through the lens of accessibility. Specifically, we will provide an overview of Universal Design for Learning (UDL), a curricular approach that has gained global popularity over the past two or three decades. We will then examine Schwanke, Smith, and Edyburn's A3 model as a framework for linking UDL with the principle of accessibility. After tracing the origins of UDL from the United States, we then argue that UDL is undergoing a period of “policy borrowing” as its principles are slowly traveling worldwide and being incorporated into national education systems. We examine this phenomenon through Armenia and Ghana, two disparate nations that have experienced the import of UDL frameworks into their national education policies or curricula. We conclude by reflecting on the limitations of UDL to seamlessly travel across contexts and offer ideas for future enactments of the pedagogical approach.

The origins of universal design for learning

Universal Design for Learning is an educational framework that draws its roots from Universal Design, a set of architectural guidelines originally coined by Ronald Mace from North Carolina State University to support the development of built environments that can be used by all individuals without the need for special adaptation. Universally Designed environments are characterized by seven core principles, among which are equitable, flexible, and intuitive use ([Center for Universal Design, 2008](#)). One example of Universal Design in practice is the construction of ramps as an alternative to stairs. Ramps can support people using wheelchairs, just as they can be accessed by parents pushing strollers, people carrying heavy groceries, or older people walking with canes. In other words, there is no need for special or adapted environments when they are constructed in consideration of all people's needs in the first instance.

In the same light, Universal Design for Learning promotes diverse learning opportunities for all students that respond to their diverse learning needs. The Center for Applied Special Technology (CAST) began applying Universal Design principles to curriculum frameworks in the early 1990s as a way of designing educational approaches that are inherently inclusive of all learners. UDL principles are linked to research in neuroscience, which recognizes that there is variability in the way all people learn, and that learning is context-dependent, such that the same person might learn in different ways depending on the subject and situation ([Meyer et al., 2014](#)). Drawing from three of the networks that guide learning in the brain—(1) affective, (2) recognition, and (3) strategic—UDL as a curriculum framework suggests that learning environments should provide all students with (1) multiple means of engagement, (2) multiple means of representation, and (3) multiple means of action and expression ([Meyer et al., 2014](#)). At the core of UDL is the assertion that learners will benefit from multiple avenues and options to participate in their education.

Just as UDL recognizes the benefits afforded by diversity and variability in learning, so too are the strategies to apply UDL in instruction diverse and variable. The principle of multiple means of engagement emphasizes learner autonomy and choice; authentic and relevant content that respects culture, age, and other identities; and scaffolding to learners to monitor their progress, set goals, and receive feedback. Multiple means of representation requires the provision of content through multiple modalities such as hearing, vision, and touch; the use of multimedia such as charts, diagrams, and illustrations; and other cues to facilitate

learning such as mnemonic devices, checklists and organizers, or concept maps. Finally, learners using multiple means of action and expression should have a choice in how they show their understanding, such as physical movement, speaking, writing, or drawing; and alternative technologies such as adapted keyboards, text-to-speech software, or graphing calculators (CAST, 2018).

As a means of delivering flexibility and variability in instruction, assistive technologies and digital media serve as useful resources in implementing UDL, where available. This includes assistive and augmentative communication that supports learners with and without disabilities, such as those who use computer or tablet apps to express themselves orally, or any number of electronic books, podcasts, presentation software, or games and stories available digitally. There is also a substantial research base demonstrating the utility of assistive technologies for students with learning disabilities, such as word processing, multimedia, and hypertext interventions (Perelmutter et al., 2017). However, many of these technologies require a level of resourcing—such as internet connectivity and reliable electricity—that are not available to all learners across the globe. Nonetheless, UDL has also been used in environments with few material resources, through numerous strategies such as small group work, the use of no-cost manipulatives found in the environment, or games and songs that promote learner engagement (Hayes et al., 2018).

Universal design and access to curriculum

The linkage of a set of pedagogical practices to the democratization of education can be explained through Schwanke, Smith, and Edyburn’s A3 model. The A3 model was used to predict the politics and practice of inclusive education, especially as it relates to children with disabilities. The model itself follows educational development through three phases: advocacy, accommodations, and eventually accessibility. Schwanke et al. (2001) argued that the democratization of knowledge begins when advocacy efforts are present. In the case of children with disabilities, advocacy for greater access to the national or local curriculum has been led by parents of children with disabilities, organizations of persons with disabilities (OPDs), and children themselves. Schwanke et al. (2001) and later Edyburn (2010) observed that an outgrowth of advocacy work is that the needs of children with disabilities are identified in schools and individualized accommodations are made for them. Accommodations are designed to provide access to curriculum, by providing individual students with a degree of flexibility in terms of timing, response, how content is presented, length of assignments, or even the location where particular educational activities take place. For example, a student may receive extended time to complete an assignment, may be allowed to use a scribe if writing is a challenge, may have assignments read to them (by humans or through technology) if decoding print is impossible, or students may be allowed to sit in a quiet space if particular classroom activities are over-stimulating.

The final stage of Schwanke et al.’s (2001) A3 model is “accessibility.” As noted in the paragraphs above, accessibility is a general principle derived from architectural access that has been applied to education. Educational accessibility seeks to provide all students with opportunities to engage with their national curriculum, with minimized needs for stigmatizing accommodations. Within a universal design framework, individualized accommodations do not disappear, but become less noticeable because many of the changes described above become available to all students, not just students with disabilities. Therefore, curriculum and access to it are of central importance in a universal design framework, rather than an educational focus on the tasks associated with curricular learning. Fig. 1 (below) provides an overview of how Schwanke et al.’s model helps to explain the development of UDL.

Accessibility, as the end goal of advocacy work and inclusion through individualized accommodations, is typically synonymous with a UDL approach. For example, according to the US Higher Education Opportunity Act (2008: 102–24):

The term Universal Design for Learning means a scientifically valid framework for learning that (A) provides flexibility in the way information is presented, in the ways students respond to demonstrate knowledge and skills, and in the way students are engaged; (B) reduces barriers in instruction, provides appropriate accommodations supports, and challenges, and maintains high achievement for all students, including students with disabilities.

UDL is not the only way to provide “accessibility” of the curriculum for students but has become a popular technical solution for engaging students within a broader movement in the field of education. As narratives of “all means all” continue to emerge in educational circles (UNESCO, 2020), some scholars have begun to further associate the concept of accessibility as an antidote to

Advocacy	Allies of children with disabilities politically fight for the right to access to an inclusive curriculum.
Accommodations	If advocacy efforts are successful, disabilities may dictate that children need individualized adjustments or accommodations to allow for full participation.
Accessibility	As teachers and fellow students become comfortable with the diversity of engagement with the curriculum, accessibility is built into everyday teaching and learning activities, which may benefit all children.

Fig. 1 Development of UDL and access to curriculum. Adapted from Schwanke et al. (2001).

systemic “ableism”—a form of discrimination inflicted by people without disabilities onto people with disabilities (Hehir, 2007; Powell, 2013). UDL, then, has become an approach that can be championed for curricular and broader societal goals within educational settings.

Interpreting UDL in practice

As UDL’s popularity grew in Northern countries, however, so did emerging debates about how to specifically enact it in schools. For example, organizations like CAST frequently distribute guidance on how UDL can be implemented in classrooms, examples of curricular interventions, and underlying psychological research that validates how accessibility approaches can work to support children (CAST, 2018). Other scholars, however, view UDL as more of an educational philosophy meant to democratize access to the goods of education and critique the use of checklists, toolkits, and how-to manuals. For example, Disability Studies scholar Jay Dolmage (2015) critiques the use of prescribed checklists and encourages educators to engage with UDL critically, examining structures that inhibit student learning, and relying on both teacher reflection and collective idea generation as ways to promote accessibility. And, as the phenomenon of UDL expands globally, others caution that UDL should not be simply equated to the provision of an inclusive education, as additional supports for specific learners may still be needed in a universally designed classroom environment (International Disability Alliance, 2021).

The debates, promises, limitations, and checklists associated with Universal Design have primarily emerged from Northern countries. Schwanke et al.’s (2001) work, for example, is based in the United States, as was the setting for Rose and Meyer’s (2002) groundbreaking conceptualization of UDL. The above-mentioned work by Powell took place in a higher education institution in Europe, and Dolmage’s vision of a critical UDL approach was framed from a Canadian perspective.

The conceptualization of UDL as an outgrowth of architectural concepts also began in the United States, as did original policies that named UDL as an approach to meeting legal demands for accessible education of children with disabilities. For example, Universal Design for Learning (UDL) emerged in the United States as a policy initiative in the late 1990s and early 2000s. In 1997, the Individuals with Disabilities Education Act (IDEA) was reauthorized, 22 years after the original IDEA was signed by the US Congress. The 1997 version presented a stronger focus on student access to the general curriculum. The word “access” became an important pivot point for advocates of children with disabilities, and the concept of UDL began to be used by policymakers and education scholars (Orkwis, 1999). The US policy focus on “access” for children with disabilities later aligned with an increased policy focus on accountability through the No Child Left Behind Act of 2001. To meet the demands of these policy initiatives, a research agenda focused on the role of educational technologies to support curricular access was undertaken by scholars interested in inclusion and UDL in the United States (Edyburn, 2005; Pisha and Coyne, 2001; Rose and Meyer, 2002).

Policy borrowing and UDL

Over the two decades following the adoption of UDL frameworks in American educational policies, the concept of UDL began to “travel” around the world, through a process of borrowing and incorporation of principles and practice. Around the same time, Ochs and Phillips (2004) attempted to conceptualize the process of “policy borrowing.” In an article in the journal *Comparative Education*, the authors acknowledged that the concept of policy borrowing was controversial, and recognized that the concept is sometimes characterized by a process of “lending” (Steiner-Khamsi, 2004), as at times governmental and other actors actively import educational approaches while at times external actors “lend” policies through provision of grants, technical assistance, or other conditional loans. In the following section, we will draw upon the concept of policy borrowing to help explain how UDL has traveled worldwide as part of a broader global movement toward enhancing inclusive education for all students through the provision of an accessible curriculum.

Ochs and Phillips (2004) conceptualization of policy borrowing is useful because the authors present four phases as a theoretical framework designed to analyze how the process occurs. The authors argue that there is often an “attraction” between two societies that stimulates the flow of educational ideas. This attraction, according to Phillips and Ochs, might be in relation to the perceived ability of the new policy or practice to meet local needs. It is likely that the policy/curricular attraction of UDL could fill many gaps, as it at once relates to a philosophy (equitable opportunity), an ambition (accessibility), and an educational approach (multiple means of classroom engagement). Phillips and Ochs argue that once the policy attraction is developed, there is a decision to adopt, a period of early implementation of the policy/innovation as it looks in the “lender” society, then an eventual “indigenization” of approaches as policies/innovations are attempted and scrutinized within particular national contexts (Ochs and Phillips, 2004).

Policy travel, UDL, and education for all

The policy attraction of UDL is related to the concept of inclusive education. The concept of inclusive education is for all children, but specifically serves as a strategy for educating children who are marginalized in education systems, including children with disabilities. Inclusive education was first identified as a practice that would help increase the chances of success of Education for All movements that began in the early 1990s. Delegates at the Salamanca Conference on Special Needs Education identified that the most appropriate way to educate a child with special educational needs was to provide access and support in regular education environments (UNESCO, 1994). The concept of inclusive education gained traction both because it aligned with existing

educational initiatives (i.e., Education for All), but was also framed as a more cost-effective option for governments than building separate facilities for children with specific educational needs.

Although the concept of inclusion as outlined in UNESCO’s *Salamanca Statement and Framework on Special Needs Education* (1994) mainly focused on access to schooling, increased focus on access to curriculum once children arrived in school soon followed. In the years that followed the *Salamanca Statement*, scholars began to identify the substantive changes that would be required for inclusive education to occur. Lena Saleh (1999), for example, stated that holistic changes must occur in order to meet the recommendations of the *Framework*, including “genuine changes in all aspects of the school’s programs—curriculum, pedagogy, organization, assessment, staffing, school ethos and school support” (1999: 209). Similar calls for educational change occurred after the Convention on the Rights of Persons with Disabilities (CRPD) (United Nations General Assembly, 2006). CRPD, which, at the time this article was written, was signed by 182 countries, called for access to the general education curriculum for children with disabilities. It wasn’t until General Comment 4 on CRPD, which was negotiated by ministerial and civil society representatives in 2016, however, that Universal Design for Learning was foregrounded as a pedagogical approach for ensuring access to curriculum. The Committee on the Rights of Persons with Disabilities encouraged States parties to

apply the Universal Design for Learning (UDL) approach. UDL is a set of principles, providing teachers and other staff with a structure to create adaptable learning environments and develop instruction to meet the diverse needs of all learners. It recognizes that each student learns in a unique manner and involves developing flexible ways to learn: creating an engaging classroom environment; maintaining high expectations for all students, while allowing multiple ways to meet expectations; empowering teachers to think differently about their own teaching; and focusing on educational outcomes for all, including those with disabilities. Curricula must be conceived, designed and applied to meet and adjust to the requirements of every student, and providing appropriate educational responses. Standardized assessments must be replaced by flexible and multiple forms of assessments and recognition of individual progress towards broad goals that provide alternative routes for learning (2016: 9).

Explicit mention in United Nations proclamations and treaties does not necessarily guarantee that an educational concept is borrowed, lent, or transferred, but the practicality of UDL as a means for meeting broader-level societal goals of access to the general curriculum for students with disabilities soon after CRPD began to be chronicled in national examples in Europe, Asia, South America, and Africa and was framed as a new “paradigm” for learning (Ostroff, 2011). This new paradigm appears to either be developing as a result of newly made commitments to inclusion and accessibility or as an updated strategy to previous (yet similar) initiatives such as Child Friendly Schools (UNICEF, 2009), student-centered learning, and adaptive learning. The extent to which UDL has been appropriated into existing initiatives is unknown, but because UDL has a specific context from which it started and has specific terminology, analysis of policy travel is transparent. In the following paragraphs two national examples are provided based on this article’s authors’ experiences. The cases of Armenia and Ghana show different processes for the adaptation and adoption of UDL as examples of how Ochs and Phillips (2004) concepts are influenced by contextual realities such as political trends, resources, and external partnerships.

National case studies

In the paragraphs below, we present two national examples of the borrowing of UDL. Although the Republic and Armenia and Ghana operate education systems in two very different contexts, they are united in their attempts to apply UDL in educational frameworks for learners with diverse needs. After describing the case of each country, we will analyze the linkage between UDL and policy borrowing.

The Republic of Armenia, like many countries in Central and Eastern Europe, has had a long history of institutionalization of students with disabilities, which gradually evolved into a system of special schools available to parents seeking therapeutic interventions. Recent changes in Armenian law demonstrate that the push toward inclusive education is slow and measured, with a policy reluctance to adopt full inclusion. Armenia’s 2015 Law on Education, for example, does not even mention “inclusion” but rather gives parents the choice of where and how to educate their child with a disability, stating that “The education of children in need of special conditions for education may be provided upon the choice of parents both at common institutions of general education and special institutions through special programs” (Republic of Armenia, 2015: Article 19.3). Despite the slow policy adoption of inclusive education at the national level, there has been a large degree of “lending” and reinterpretation about inclusive education, UDL, and access to curriculum by international agencies (e.g., UNICEF), international non-governmental organizations (NGOs) (e.g., Open Society Foundation), and their Armenian counterparts (e.g., Education and Research Foundation, Armenian Center for Democratic Education). These organizations have pushed for greater inclusion of children with disabilities through inclusive pedagogy and accessible curriculum.

The Armenian State Pedagogical University, for example, recently adopted a textbook and coursework for training its preservice teachers that includes UDL (Tichá et al., 2019). A forthcoming article (Avagyan et al., 2021) contextualizes UDL in Armenia, framing it as a mechanism to provide all children with access to content related to Armenia’s history and civic traditions. The case of Armenia demonstrates that despite a policy attraction to international treaties (the Republic of Armenia signed the CRPD in 2010), histories and interpretations of inclusive education vary, as indicated by language of “choice” in Armenia’s laws. Further, the concept of UDL, based on emerging evidence, appears to be one embraced by civil society and non-governmental groups, including Teach for

Armenia (Miller, 2019), but is not a core governmental educational initiative. The journey of UDL, then, could be seen as one that has traveled to Armenia, is being both promoted by international non-governmental organizations and adopted by national NGOs, but has yet to, and may never, achieve policy significance in Armenia.

In Ghana, the recent implementation of UDL on a pilot basis in select schools is underpinned by decades of policy and programmatic change in special and inclusive education. This includes the 1992 Constitution of Ghana, 1998 Children’s Act, and the 2006 Persons with Disability Law, which all recognize the right of children with disabilities to an education (Avoke and Hayford, 2017). In practice, children with “severe” disabilities—categorized as those who are deaf, blind, or have intellectual disability—continue to be educated in segregated schools, a practice that neither the more recent 2015 Inclusive Education Policy nor the 2010–2020 Education Strategic Plan have explicitly challenged (Avoke and Hayford, 2017; Government of Ghana, 2012, 2015). The policy-level reinforcements of segregation for some learners, along with unspecific strategic planning on the transformation of mainstream education environments into truly inclusive settings, has been accompanied by an observation that these plans have not thoroughly considered the changes needed in teaching approaches to effectively include all learners (Nketsia, 2019). This challenge is compounded by a national system of identifying disabilities that remains “confusing, ineffective, and inefficient,” which is in turn linked to the rare practice of formally diagnosing a child with a disability in Ghana (Avoke and Hayford, 2017, p. 360).

One programmatic initiative responding to this concern about teaching approaches was UNICEF’s import—or arguably, borrowing—of its global child-friendly schools model to Ghana in the early 2000s (Chabbott, 2004). The principle of child-friendly education was then reflected in both the 2015 Inclusive Education Policy and the 2010–2020 Education Strategic Plan. Further to this support to child-friendly schools, UNICEF collaborated with the Ghana Education Service to pilot inclusive education activities across the nation, which has helped to produce over 2000 mainstream schools practicing inclusive education in Ghana (Ministry of Education, 2015).

Beginning in 2012, Ghanaian Professor Samuel Hayford presented the concept of UDL in Ghana, after he had learned about it through his Ph.D. studies in England. He also embedded it into the graduate education coursework taught at the University of Education, Winneba (personal communication, 2020). Ultimately, through support from Dr. Hayford, UNICEF, the Ghana Education Service, and others, the 2015 Inclusive Education Policy proclaimed the overarching goal of the policy is to “respond to the diverse needs of all learners within the framework of Universal Design for Learning and Child Friendly School Concept” (Government of Ghana, 2015, p. 3). An inclusive education framework founded in the principles of UDL has laid way to the piloting of a UDL pedagogical approach by 15 Ghanaian primary school teachers over the 2019–2020 schoolyear (Hayes, 2019; Niad, 2019). The Ghana Education Service and its National Teaching Council have since expanded the initiative on a national basis through the embedding of UDL into existing in-service training programs, an approach that may support sustainability as compared to treating UDL as a standalone topic.

The examples from Armenia and Ghana illustrate that educational policies (or strategies) such as UDL are often first brought in by external actors. In these cases, UNICEF was instrumental in establishing inclusive education ideals and the strategies that follow. In the case of Armenia, local civil society organizations picked up on examples, adapted them to local educational conceptions of public value, and implemented through training and outreach. Further, university faculty engaged in international projects began to adapt and adopt UDL content in pre-service teacher training. In Ghana, the combination of an external actor (UNICEF) and a local champion with international experience made possible the dialogs on UDL that eventually led to policy shifts that were scaled up across the country.

Conclusions

The case of UDL as a mechanism for providing widespread access to curriculum and education appears to follow some of the same patterns identified by Ochs and Phillips (2004). These patterns, according to the authors, are predictable. A global movement toward inclusiveness and access to education for children with disabilities is underway and the concept of UDL appears to be at once a guiding philosophy, ambition, strategy, enabling structure, attractive process, and new technique that has traveled well. The cases of Armenia and Ghana, however, highlight the limitations of UDL as a borrowed concept.

In both nations, there are gaps in policy in relation to supporting access to national curriculum for students with particular types of disabilities. In this case, the concept of inclusion for “all” still has asterisks for children with particular disability types. It is quite possible that the continued exclusion of children with particular disabilities from inclusive schools is also a relic of policy borrowing, either from the hyper-medicalized and segregated education system of special education brought to Central and Eastern European countries by the Soviet Union, or the charitable (and equally medicalized) system of segregated education brought to Ghana by European missionaries.

In many ways, UDL is a sign of the times. It provides a nicely packaged set of principles that can be adapted across educational settings to provide access to curriculum for children with disabilities alongside all other peers from their communities. Where UDL has fallen short in Armenia, however, is its potential for transforming curricular access for children with significant disabilities and the degree to which it has reached significant scale in its new host countries. In theory, accessibility should facilitate for inclusive classrooms that allow for any child to experience schooling in a way that is adaptable, flexible, and meets their needs. In practice, many of the early examples for UDL focused on children with reading and attentional disabilities (see Rose and Meyer, 2002), so when it traveled it did not have an impact on children with more significant learning challenges. Therefore, Ochs and Phillips (2004) concept of “synthesis” of UDL into existing systems of Armenia and Ghana, but also failed to create transformative change

for children with the most significant disabilities. This limitation may be the result of the borrowing process itself or lack of political will within countries to attempt inclusion for all students.

The story of UDL and policy borrowing for Armenia demonstrates both its promise and shortcomings. Readers may ask how children with significant disabilities can then be included if the concept of UDL has not yet facilitated such inclusion. The answer may lie in Schwanke et al.'s (2001) A3 model. While children with mild to moderate disabilities are now experiencing a universally designed curriculum in many areas of the world, a strategy for children who have not yet had such opportunity may be to return to “advocacy”.

According to Schwanke et al. the very first step in supporting accessible curriculum is to advocate for the inclusion of all children. This work has already begun in Armenia by parents and organizations of persons with disabilities. If and when these advocates are successful, there will likely be a period when students are accommodated individually as teachers adjust to expanded conceptualizations of what it means to be a member of a classroom community. With practice and support, it is feasible that teachers may then begin to think about accessibility in broader and more flexible ways than ever before. If such a learning revolution occurs in this country, the policies and practices employed may then be borrowed elsewhere, establishing a new circular flow of global policy borrowing, accessibility, and universal design for learning.

In Ghana, the day-to-day aspects of UDL implementation are slightly different than Armenia, but land in a similar place in terms of the continued need for advocacy for children with significant disabilities. Disability screening and identification is in a nascent stage in Ghana right now, as new policies and practices emerge which are aimed at finding and supporting children with disabilities. In this way, UDL has worked well as an approach to supporting all children who are “casually integrated” (see Miles, 1997) into Ghana’s mainstream education system. Unlike foundational UDL logics based in the US that aimed to support inclusive education for children with mild to moderate disabilities through creating accessible classrooms, in Ghana accessible classrooms are often a starting point for teachers who may have little diagnostic information on the children in their classrooms, including a common absence of basic hearing and vision screening. In many ways, this lack of identification allows for a leapfrogging in Ghanaian classrooms, where accessibility can flourish without a need for disability labels. In the A3 model, a system without labels for those with less significant disabilities might go directly to “accessibility” without needing prerequisite advocacy or accommodations. Such leapfrogging at once creates a model case for accessibility, but, as mentioned above, may be limited by traditional models of segregated education or lack of access to schooling at all for children with significant disabilities. In this case, advocacy and accommodations would benefit by supporting the increased entry of such children into schools, who could later be supported by UDL and other relevant strategies.

In conclusion, inclusive education and curriculum are two tightly wound initiatives. No system can claim to serve the public unless it is accessible to all of its members. UDL is one approach to ensuring that education can be accessible to all participants in an educational setting. It has shown great promise in the United States by equipping mainstream education environments with strategies to promote inclusion of learners with disabilities, and has subsequently traveled around the world, including two countries with relatively little in common—Armenia and Ghana. Our review of UDL and the borrowing of its concepts reveals two considerations for further research. First, UDL appears to be an intuitive approach to creating accessibility and can be easily applied in both systems with robust identification of children with disabilities and systems in which children’s needs are not specifically labeled, but may be recognized by teachers. In either setting, UDL can work, but the path to accessibility may be different. The second consideration for UDL as it is borrowed and travels worldwide is that more comparative data is needed on how UDL can be leveraged for access to mainstream curriculum for children with more significant sensory or cognitive disabilities.

Rao, Smith, and Lowry, for example, lamented that “Despite the fact that UDL is acknowledged as a means to further inclusionary practices for all students, UDL—and its potential outcomes for students with (intellectual disability)—has yet to be systematically considered and applied within current UDL reform efforts” (2017: 46). In this way, UDL’s promise has traveled, been locally adopted, and has provided promising outcomes worldwide. At the same time, its limitations have traveled, creating space for a new wave of localized, contextualized research on how a concept like UDL can be applied for new populations. Such research may “borrow” and “expand” UDL or may have an entirely new set of terms and applications. Either way, “all” still does not mean “all” in 2022 as children with some forms of disabilities continue to be excluded from their national curriculum.

EDITORS IN CHIEF – BIOGRAPHIES

Robert J Tierney

Rob Tierney is an international educator whose passion is for developing research partnerships to address local literacy needs with educators in different countries. Rob began his career as a classroom teacher in Australia, then proceeded to work in the United States, Canada, Australia and China. He is Dean Emeritus and Professor Emeritus of Language and Literacy Education at the University of British Columbia, the former Dean and Honorary Professor of the Faculty of Education and Social Work at University of Sydney, and a Distinguished University Professor at Beijing Normal University. In the United States, he has served on the faculties of the University of Illinois, University of Arizona, The Ohio State University, Harvard University, and the University of California. Rob has written a number of books and numerous articles on literacy especially related to global issues, diversity, and literacy development. His most recent book was entitled *A History of Literacy Education: Waves of Research and Practice* published by Teachers College Press in 2021. During his tenure as an educator, he has served as the President of the International Literacy Association, President of the Literacy Research Association, an Editor for the *Reading Research Quarterly*, the President of the Association of Canadian Deans of Education/ L'Association Canadienne des Doyens et Doyennes d'éducation, as well on a number of committees and boards for professional groups and government and nongovernment

agencies. In addition, he has been involved on a range of groups on projects globally including in Africa and Asia including for UNESCO, Children's Television Workshop, and Apple Computer.

Fazal Rizvi

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia–Asia relations. He has published widely, and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge 2010) is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge 2022) has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

**Kadriye Ercikan**

Kadriye Ercikan is Vice President of Research and Measurement Sciences at the Educational Testing Service and Professor Emerita at the University of British Columbia. She is responsible for ETS's foundational and applied research and psychometric support of ETS's major testing products and contracts, and the NAEP contract for ETS. Her research focuses on validity and fairness issues and sociocultural context of assessment. Her recent research includes validation of score meaning using response processes, use of response process data for comparing groups and examining fairness and validity of interpretation, and use of scores from artificial intelligence-based automated scoring.

Ercikan is a Fellow of the International Academy of Education. Her research has resulted in 6 books, 4 special issues of refereed journals, and over 100 publications. She was awarded the AERA Division D Significant Contributions to Educational Measurement and Research Methodology recognition for another

coedited volume, *Generalizing from Educational Research: Beyond Qualitative and Quantitative*

Polarization, and received an Early Career Award from the University of British Columbia. Ercikan has been selected to serve as the NCME Book Series Editor (2021–2026).

EDITORIAL BOARD

Jason Beech

SECTION EDITORS

Jason Beech is Associate Professor (Global Policy) at the University of Melbourne and visiting professor at Universidad de San Andrés in Buenos Aires where he holds a UNESCO Chair in Education for Sustainability and Global Citizenship. He is senior researcher of the National Council for Scientific and Technical Research of Argentina (CONICET), and Associate Editor of *Education Policy Analysis Archives*. He has been a member of the Board of Directors of the Comparative and International Education Society (2014-2016). Jason has published extensively on the globalization of knowledge and policies related to education. He has also written and is passionate about the challenges of educating for global citizenship and a sustainable future. He has taught in several universities in the Americas, Europe and Australia.

Professor Qing Gu is Director of the UCL Centre for Educational Leadership and Professor of Leadership in Education. She is the Past Chair of the *British Association of Comparative and International Education* (BAICE), Co-Editor of *Teachers and Teaching: Theory and Practice*, Associate Editor of *International Journal of Educational Development*, a member of the Research Standing Committee of the World Council of Comparative Education Societies (WCCES), and a member of the Research Evidence and Impact Panel for the Leadership College for UK Government. Professor Gu has directed and codirected many government and research council funded projects in the areas of teacher professional development, school improvement, and systemic reform and change. She has led a £1.9 m UK Economic and Social Research Council (ESRC) funded project *Schools as Enabling Spaces to Improve Learning and Health-Related Quality of Life for Primary School Children in Rural Communities in South Africa*. Some of her books have been translated into Chinese, Japanese, and Spanish.

Professor Smith is a New Zealand Maori of Te Aitanga a Hauiti, Ngati Porou, Kati MamoeNgati Apa, Ngati Kahungunu descent. He is a highly regarded and internationally recognized, Maori educationalist and scholar. He has been at the forefront of transforming Maori and Indigenous social, economic and cultural conditions through re-developing education and schooling outcomes. His work links theoretical thinking and practical applications within an ongoing cycle of transforming praxis.

Professor Smith trained as a teacher at Auckland Teachers College and taught in Auckland schools. He also lectured in Education at the Auckland College of Education. He was one of the first teachers and developers of a Kura Kaupapa Maori, an alternative, Maori philosophy and principles-based School. These Maori immersion schools have grown from a single entity in 1988 to over seventy-five publicly funded schools in 2015. His theoretical leadership in the Education Department at the University of Auckland helped inform the emergence of Maori Education as a distinct field of study across the New Zealand Tertiary Sector. This work has encouraged a wide range of academic studies focused on overthrowing persisting inequities within and as a result of education and schooling in New Zealand. His significant contribution to New Zealand education is to be seen in his work related to Kaupapa Maori as a theory of Transformative Praxis. All of these elements derive from his PhD research entitled, "The Development of Kaupapa Maori: Theory and Praxis (1997)".

Professor Smith's later academic work centered on developing theoretically informed strategies related to transforming high and disproportionate levels of Maori cultural, political, social, educational, and economic marginalization. He has been a significant scholar involved in the emergence of Tribal "university" institutions (Wananga) and is the former foundation Chair of the Council for Te Whare Wananga O Awanuiarangi. He led the successful Treaty of Waitangi Claim and settlement for Awanuiarangi. In his former position as Pro Vice Chancellor (Maori) at the University of Auckland, he was responsible for developing significant structural change within the institution while working within the Office of the then Vice Chancellor, Dr. John Hood. Notable achievements included implementing a Maori development strategy within the University which required all Deans to be responsive in their performance results for Maori and Pacific advancement; the oversight of the Proposal and winning of a National Centre of Research Excellence (Nga Pae o te Maramatanga); the initiation of the Maori and Indigenous doctoral program aimed at creating 500 Maori PhD graduates across the country in five years; the recruitment of top Maori academic scholars into the University of Auckland; the development of Kaupapa Maori as a theory of transformative praxis and which has had national and international influence. Professor Smith also served on the University of Auckland Council for three years as the Professorial representative for Academic staff.

In 2007 Professor Smith accepted a role as the Universitas 21 Distinguished Visiting Professor in Indigenous Education hosted by the University of British Columbia (within the Faculty of Education). Although the position was initially intended for two years, the role was extended for a further three years. While situated at the University of British Columbia, Professor Smith also chaired the Educational Policy Studies Department for three years. These positions allowed engagement with many Canadian universities as well as other universities across the world.

Professor Smith has made significant contributions to the political, social, economic, and cultural advancement of Maori and indigenous communities in New Zealand and around the Pacific Rim. He has worked extensively with other Native/Indigenous/First Nation's peoples across the world, including in Canada, India, US mainland (including extensive work in Hawaii and Alaska), Norway, Taiwan, Chile, Australia, as well as with selected Micronesian and Pacific nations. He is a regular contributor to national and international forums and conferences. Professor Smith has been an authoritative voice within the critical debates on *social, cultural and economic inequality* both in New Zealand and abroad, and he maintains a strong influence in the Maori/Indigenous languages revitalization movements.

Professor Smith stepped down from the administrative position of CEO/Vice Chancellor at Te Whare Wananga o Awanuiarangi in 2015 after eight years in the role. He resumed his academic research and writing career. In 2019 he was invited to take up a special Chair – Te Toi Ihorei ki Purehuroa – A "distinguished Professorial position at large" established for him at Massey University.

Professor Smith has been recognized and honored for his international contributions, receiving an Honorary doctorate (D.Litt.) from the Okanagan University College in 2005, and an Honorary doctorate (LLD) from the University of Northern British Columbia in 2013; he was elected as a Fellow of the American Education Research Association in 2014, and was awarded a Queens Honour – a CNZM in 2014. He was given the Prime Minister's Life-time Achievement Award (2017); and received the Te Ururangi National Award for Education (Matariki Awards, 2019).

Professor Smith is married to Professor Linda Tuhiwai Smith and they have one daughter and two mokopuna (grandchildren).

Therese N. Hopfenbeck is Professor of Measurement Analytics in the Melbourne Graduate School of Education, The University of Melbourne. Before starting her position in Melbourne, she was Professor in Educational Assessment and Director of the Oxford University Centre for Educational Assessment. She is a Visiting Fellow at Kellogg College, University of Oxford, elected Vice-President of *The Association for Educational Assessment-Europe* and Lead Editor of the journal *Assessment in Education, Principle, Policy and Practice*. Dr. Hopfenbeck's research agenda focuses upon bridging research on self-regulation and classroom-based assessment and making sense of international large-scale studies in education. In collaboration with Professor Nancy Perry, University of British Columbia, she is currently leading an international network of researchers disseminating classroom-based research, funded by Social Sciences and Humanities Research Council of Canada (2020–2022). She is also currently Principal Investigator for two research projects funded by IB, on critical thinking in PYP schools internationally and evaluation of education reforms in Kent, UK (2020–2022). In 2020, she led the research on Critical Thinking in the Diploma Program in Australia, England, and Norway (<https://ibo.org/research/outcomes-research/diploma-studies/critical-thinking-skills-of-dp-students/>). Dr. Hopfenbeck was Principal Investigator for the PISA (2022) study in England, Northern Ireland, and Wales, in collaboration with Pearson UK (2018–2023). She was the Research Manager of PIRLS (2016), funded by The Department of Education, UK.gov, and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019).

Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). She has advised on the implementation of formative assessment programs in India, South Africa, Norway, and the Emirates and carried out policy work for UNESCO/OECD and the Norwegian Ministry of Education Norway. Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

Nataliya Ivankova, PhD, MPH, is Professor in the School of Health Professions at the University of Alabama at Birmingham (UAB). As an applied research methodologist working at the intersection of mixed methods, qualitative, community-based, action, and translational research, she is internationally recognized for her empirical and methodological publications. She shares her research expertise through teaching mixed methods and qualitative research courses, conducting workshops and guest lectures, mentoring doctoral students and junior faculty, and serving as key personnel on funded research projects. At UAB, she directs an online graduate certificate program in *Applications of Mixed Methods Research* and oversees the design and analytical aspects of qualitative and mixed methods studies through the Center for Health Informatics for Patient Safety and Quality. She is a founding Coeditor of the *Mixed Methods Research Series* (Sage) and serves as an Associate Editor for the *Journal of Mixed Methods Research*.

Professor Jahnke is Director of Toi Kura Centre for Maori & Indigenous Education. She was the 2019 inaugural Toi o Te Wananga Fellow. Professor Jahnke holds professional qualifications in education and is cofounder and immediate past Chair of the Indigenous Peoples of the Pacific Special Interest Group of the American Education Research Association (AERA). She currently serves on the AERA Executive Committee. She was a member of the Social & Human Sciences Sub Commission of the NZ National Commission for UNESCO, the NZ Bioethics Council, the NZ Ethics Committee on Assisted Reproduction Technology, and Chair of NZ Health Research Council Ethics Committee. She is currently Cochair of the Aotearoa Research Ethics Board and a Fulbright Scholar.

Berit Karseth, PhD, is Professor at the University of Oslo, Department of Education. Karseth's main research and publications lie in the field of education policy, reforms, and curriculum studies. She has edited four books and written several journal articles and book chapters in both Norwegian and English. Her most recent publications in English include articles published in the *Journal of Education Policy*, *Scandinavian Journal of Educational Research*, *Journal of Curriculum Studies*, and *European Educational Research Journal*. Karseth was the elected dean of the Faculty of Educational Sciences at the University of Oslo 2013–2016 and is currently in the leadership team of the research group Curriculum studies, educational leadership, and governance (CLEG) at the same institution.

Dr. Kenneth Leithwood is Emeritus Professor at OISE/University of Toronto and an honorary professor at the University College London and the University of Nottingham. His research and writing is about school leadership, educational policy, and organizational change. He has published extensively on these topics. For example, his most recent books include *Leadership Development on a Large Scale: Lessons for Long-term Success* (2018, Corwin), *How School Leaders Contribute to Student Success* (2017, Springer), and *Linking Leadership to Student Learning* (2012, Jossey Bass). Professor Leithwood is the inaugural recipient of the University of Toronto's *Impact on Public Policy* award, AERA (2011) *Outstanding Leadership Researcher Award*, the 2012 *Roald F. Campbell Lifetime Achievement Award* from the University Council for Educational Administration, and the Ontario Principals' Council *Outstanding Educator of the Year* award for 2017. He is a *Fellow of the Royal Society of Canada*. A recently published bibliometric analysis found that Dr. Leithwood was the most frequently cited, highest impact educational leadership researcher in the world.¹ Research.com's 2022 Ranking of the Top 1000 Scientists in the area of Social Sciences and Humanities ranked Dr. Leithwood 70th in the world and 7th in Canada.

Xiufeng Liu is a Professor of Science Education at State University of New York, Buffalo, and a Fellow of the American Association for the Advancement of Science (AAAS). He obtained his PhD from the University of British Columbia in 1993. Before his current position, he taught high school chemistry in China, and was a tenured faculty member at St. Francis Xavier University and University of Prince Edward Island, both in Canada. From September 2020 to August 2022, he served as a program director in the Division of Research on Learning of the National Science Foundation. Dr. Liu conducts research on measurement and evaluation of STEM education and student learning of cross-cutting concepts of matter and energy. Dr. Liu is currently a Coeditor-in-chief for the journal *Disciplinary and International Science Education Research* (Springer) and an Associate Editor for the *Journal of Research in Science Teaching*, a premier journal in science education.

Margie Maaka is a Professor of Education at the University of Hawai'i at Mānoa. Her PhD is in educational psychology. She also holds professional qualifications in education from the University of Waikato and Hamilton Teachers College. She is cofounder and current Program Chair of the Indigenous Peoples of the Pacific Special Interest Group (SIG) of the American Educational Research Association (AERA). From 2017 to 2020, she served as a member of the AERA Executive Council and Chair of the SIG Executive Committee. Before that (2014–2017), Professor Maaka served as a member of the SIG Executive Committee. She has also served as a member of the Ngā Pae o te Māramatanga Center of Research Excellence International Research Advisory Panel. Her research on community-based educational renewal saw her recognized as a national scholar with the Goodlad Institute for Educational Renewal. As Cochair of the Sovereign Councils of the Hawaiian Homelands Assembly's Committee on Education, she prepared educators and educational leaders for public schools in the Hawaiian Home Lands Trust communities. Currently, Professor Maaka is committed to the preparation of indigenous educational leaders in higher education. Her research interests include community partnerships, educational psychology/indigenous educational psychology, indigenous development and advancement, educational policy, multiliteracies, and language and cognitive development.

Diane Mayer is Professor Emerita at the University of Oxford. Her research and scholarship focus on teacher education and early career teaching, examining issues associated with the policy and practice of teachers' work and teacher education.

Daniel McCaffrey is the Associate Vice President of Psychometric Analysis and Research in the Research and Measurement Science unit of the Research and Development division at ETS. Dan's research interests include the evaluation of artificial intelligence scoring of constructed responses, developing tools and methods for causal modeling, evaluating the psychometric properties of student achievement growth measures derived from annual test scores, and methods to account for measurement error in secondary data analysis. Dan received his PhD in Statistics from North Carolina State University in 1991.

Judy Parr is Professor Emerita at the University of Auckland, Faculty of Education, where she was the founding Head of the School of Curriculum and Pedagogy. A psychologist, Dr. Parr's research program is located broadly within improvement science. Her expertise is in literacy, specifically writing and its development, encompassing instructional issues like teacher knowledge and practice and the assessment of writing. Much research has been collaborative, with colleagues and practitioners within major national projects for school improvement aimed at raising achievement in literacy and, internationally, as part of funded large-scale research projects, for example in Canada and Norway. Dr. Parr has published widely in the areas of literacy, assessment, and professional learning.

Jeong-eun Rhee is a Professor of Education, Long Island University, Post, New York. Born and raised in Seoul, Korea, she earned her bachelor's degree in Educational Psychology from Ewha Women's University. In 1992, she came to the US as an international student and received an MA in Educational Psychology from West Virginia University and a PhD in Educational Policy and Leadership from the Ohio State University. As an interdisciplinary cultural researcher and educator, her recent work focuses on developing and supporting transnational, intergenerational, and decolonial feminist knowledge projects in/through antioppressive education. She recently published *Decolonial Feminist Research: Haunting, Rememory, and Mothers*, which received an honorable mention for the 2022 Qualitative Book Award of International Congress of Qualitative Inquiry.

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge, 2010), is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge, 2022), has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

Theresa Rogers is Professor of Language and Literacy Education at the University of British Columbia. Her research interests include youth arts, media and critical literacies, adolescent literature, and teacher education in literacy. Most recently she published "Youth Activism through Critical Arts, Transmedia, and Multiliteracies" in the *Oxford Research Encyclopedia*. She is author of the book, *Youth, Critical Literacies and Civic Engagement: Arts, Media and Literacy in the lives of adolescents* (Routledge) and numerous articles in scholarly journals such as *Literacy Research: Theory, Method and Practice*, *Reading Research Quarterly*, *Pedagogies*, *Language Arts*, *Children's Literature in Education* and *Journal of Literacy Research*. See: <https://ubc.academia.edu/TheresaRogers>.

Professor Chika Sehoole is a Professor of Higher Education and the Dean of the Faculty of Education at the University of Pretoria. He obtained his PhD at the University of the Witwatersrand, Johannesburg, in December 2002. In 2003/4 he was a visiting Rockefeller postdoctoral fellow at the Centre for African Studies at the University of Illinois in Urbana Champaign. In 2005/06 he was a New Century Fulbright Fellow, again, at the same university. His research interests are in the areas of higher education policy, internationalization of higher education, higher education in Africa, and teacher education. He has served in several international research projects focusing on higher education and providing expertise from the South African and African perspectives. In 2013–2017 he served as the Chairperson of the Board of the African Network for Internationalisation of Education (ANIE). He currently serves as the chairperson of the Education Deans' Forum of South Africa. He has published a singled authored book titled "Democratising higher education policy, constraints of reform in post-apartheid South Africa" by (Routledge); three edited scholarly books on higher education and more than 40 articles in journal articles, book chapters, and popular media.

Roland Sintos Coloma is a tenured Full Professor of Teacher Education at Wayne State University in Detroit, Michigan. A scholar of history, cultural studies, and education, his research addresses critical questions of race, gender, and sexuality from transnational and intersectional perspectives. His publications include *Asian Canadian Studies Reader* (2017), *Filipinos in Canada: Disturbing Invisibility* (2012), and *Postcolonial Challenges in Education* (2009). His articles have been published in top-ranked peer-reviewed journals, including *Curriculum Inquiry*, *Discourse: Studies in the Cultural Politics of Education*, *Educational Studies*, *Educational Theory*, *History of Education Quarterly*, *International Journal of Qualitative Studies in Education*, *Paedagogica Historica*, and *Race Ethnicity and Education*. He has successfully garnered over \$2 million of external funding from federal, education, and nonprofit agencies, including the US Department of Education, National Education Association, Spencer Foundation, and Schultz Family Foundation as part of the Bill & Melinda Gates Foundation's Grand Economic Challenges. Roland has served in various university leadership roles as an assistant dean, department chair, graduate coordinator, and center codirector. He was president of the American Educational Studies Association (2018–19), editor of the *Educational Studies* journal (2014–17), and program cochair of Division G (Social Context of Education) in the American Educational Research Association (AERA). He received the 2017 Distinguished Scholar Award from the AERA Research on the Education of Asian Pacific Americans SIG and the 2015 Article of the Year Award from the AERA Queer Studies and Education SIG. In 2020, he was appointed to the Governor of Michigan's statewide Asian Pacific American Affairs Commission. Born in the Philippines and raised in California, he completed his PhD in Cultural Studies in Education and Minor in African American and African Studies from The Ohio State University in 2004.

Roger Slee is the Founding Editor of *The International Journal of Inclusive Education* and *The Journal of Disability Studies in Education*. A former Deputy Director-General of Education in Queensland, Australia, he has advised governments on inclusive education policy and practice. His published books include: *The Irregular School*; *Inclusive Education Isn't Dead, It Just Smells Funny*; and *Ethics and Inclusive Education: Disability, Schooling & Justice* (with Gordon Tait). Roger was commissioned by the UNESCO to write the scoping paper for the 2020 Global Education Monitoring Report, *Inclusion and Education*. Roger also held the Chair of Inclusive Education at the Institute of Education, London, and is now the Diamond Jubilee Professor of Disability & Inclusion in the School of Sociology & Social Policy at the University of Leeds.

Ninni Wahlström is a Professor of Education at Linnæus University, Sweden. Her current research focuses on transnational and national policy discourses and their implications for national curriculum and classroom teaching from a perspective of curriculum theory and educational philosophy. Most recent publications are "School and democratic hope: the school as a space for civic literacy" in *European Educational Research Journal* (2022) and Wahlström (Ed.) *Equity, Teaching Practice and the Curriculum*, Routledge (2022).

Lei Wang is Professor and PHD advisor of the Institute of Chemical Education, the College of Chemistry in Beijing Normal University (BNU). She is also the member of Teaching Steering Committee on Basic Education of Ministry of Education of China and the director of its branch Committee on Secondary Chemistry Education, the director assistant of Faculty of Education of BNU, vice director of the Institute of Science Education of BNU, and Chairman of the Chemistry Education Committee of the Chinese Chemical Society. She is one of the chief experts in developing the *Secondary School Chemistry Curriculum Standards* of MOE. She works as the chief editor of high school chemistry textbooks (Shandong Science and Technology Press, 2004 and 2019 editions) and junior high school chemistry project-based learning textbooks (Shanxi Education Press, 2018 edition). She achieved the first prize of the National Basic Education Teaching Achievement Award, the second prize of the National Higher Education Teaching Achievement Award, and the BAOGANG Education Outstanding Teacher Award.

Everard Weber is a retired professor. He has worked in the field of education for more than 40 years. Currently he is a research associate at the University of Johannesburg (UJ) and an academic advisor in the Future Professors Programme (FPP) at UJ. He studied African Languages and History at the University of Cape Town and Comparative and International Education at Harvard University. In South Africa he has worked at Crestway High School in Cape Town, the University of the Witwatersrand, and the University of Pretoria. A recent book is *A home away from home: a community of international and South African university students*. The FPP is a government-sponsored initiative that seeks to develop the next generation of professors and academic leaders in all disciplines, across all universities in South Africa. He is in addition presently conducting fieldwork on curriculum change in South African higher education with Professor Shireen Motala and Dr. Venise Joubert at UJ. This project is grounded in the history of southern Africa and hopes to contribute to the scholarship of postcolonialism.

Ian A.G. Wilkinson is Professor in the Department of Teaching and Learning at The Ohio State University and Honorary Professor in the School of Curriculum and Pedagogy at the University of Auckland, Aotearoa/New Zealand. He has a background in educational psychology with special interests in cognition, instruction, and research methodology as they relate to the study of literacy. He served as coauthor of the influential report, *Becoming a Nation of Readers* (National Academy of Education, 1985). He was Co-Editor of *Reading Research Quarterly* from 2006 to 2012 and was inducted into the Reading Hall of Fame in 2021. His research examines the impact of classroom discussion and dialogue on students' reading comprehension and argument literacy and the implications for professional development of teachers. Recently he coauthored books include *The Most Reasonable Answer: Helping Students Build Better Arguments Together* and *Quality Talk About Text: Discussion Practices for Talking and Thinking About Text*.

David B. Yaden, Jr., PhD, is the *Jewell M. Lewis Endowed Distinguished Professor of Literacy* in the Department of Teaching, Learning and Sociocultural Studies at the University of Arizona. Prior to his present position at the University of Arizona, he held appointments at Emory University, the University of Houston, and the University of Southern California. He served as Co-Editor of the *Journal of Literacy Research*, one of the premier research journals in the field of literacy studies, and was a Principal Investigator in the federally funded Center for the Improvement of Early Reading Achievement (CIERA) where he implemented an early literacy curriculum for linguistically diverse preschoolers in inner-city Los Angeles. He also directed a statewide consortium of researchers from Arizona's major universities in the evaluation of the state's early childhood initiative to evaluate health, developmental, and educational factors contributing to school readiness. His research interests and specializations include developmental issues in early childhood education, the acquisition of literacy and biliteracy in young emergent bilingual children, family literacy, theories of reading disability, microgenetic research design, and the application of complex adaptive systems theory to growth in reading and writing.

Volume 8: Higher Education Management, Policy, and Practice

Chika Schoole and Everard Weber

© 2023 Elsevier Ltd. All rights reserved.

Introduction

In recent years, several encyclopedias and handbooks such as the third edition of this encyclopedia have been published, addressing the emerging forms, practices, and issues of higher education. Most of these works, however, focus on shifts in higher education policy, management, and practice in the Global North. In so far as the descriptions of the systems of higher education in the Global South are concerned, much of where the interest lies is in economically advanced countries such as Singapore, South Korea, and Hong Kong and in the rapidly developing system of higher education in China. Little attention is paid in these encyclopedias and handbooks on the less developed systems, and when it is, it is invariably articulated in the language of challenges and barriers to reform, and their under-developed condition. This volume of the *International Encyclopedia of Education* is constructed deliberately to overcome this gap in the literature. It is edited from South Africa, with a number of papers included in it exploring issues of higher education as they are faced by various countries in Africa. Many other papers moreover examine the broader global issues in higher education from an African perspective, while others still could be viewed as an invitation to consider how global developments are interpreted and affect policy development in systems of higher education systems in the Global South, and their contribution to higher education's global architecture.

Higher education has for centuries been associated with the imperatives of societal development through educating individuals at a higher level, as well as through knowledge creation and advancements in the sciences and humanities. Before World War II, the forces of industrialization and modernization stimulated the establishment of higher education institutions (HEIs) to meet the requirements of emerging societies, not only in the Global North but also some parts of the South, where HEIs were created to serve colonial interests. After World War II, however, higher education in the Global South has widely been viewed as a major driver toward national development, supported by United Nations institutions and multilateral development banks. This period has also seen the emergence of a series of ideas and institutions in the Global North and on how the Global North could bring more development to the Global South. According to Aydin (2014) this changing relationship led to the emergence of the field of international development, as higher education and the ideas of social and economic development became intractably linked. Higher education has not been used only for national development; but after World War II, with the emergence of the Cold War, International Relations became shaped by a confrontation between the United States and Soviet Union, an East-West confrontation framed by divergent models of their respective political systems, economic systems, and ideologies. In this context international aid programs became a major part of the strategy to win over the "minds" and "allegiance" and to reproduce or transform foreign dominant groups (Tsvetkova, 2008).

After World War II, the western knowledge systems continued to dominate higher education policies and practices in the Global South, as a strategy to forge the "minds" of local populations capable of working toward development objectives. There is critique, for example, by Serian et al. (this volume) of the use of English as the unproblematic language of instruction, with a suggestion that if indeed an equitable, societally beneficial, and high-quality "education for all" is to be a major goal of higher education, it needs to be embedded within a larger processes of global knowledge systems in which English plays a hegemonic role. In more recent decades, the colonial assumptions persist even as aspirations of decolonization have acquired considerable currency. Within the Global South, the discourses of internationalization have become popular, but carry with them a range of dilemmas and contradictions.

It is with a deep awareness of the dilemmas and contradictions associated with the competing agendas of internationalization and localization that the papers in this volume examine issues of policy governance and leadership; internationalization; curriculum, teaching, and learning; diversity, inclusion, and equity; and labor markets and vocational education and training. The papers on curriculum, diversity, and labor markets are located within the broader discussion regarding, for example, globalization and decolonization. The latter, in other words, contextualize the former and we hope deepen analyses at the institutional level and at the level of practice. By this we do not mean to suggest the local developments are a function of historical or international policy change. Case studies in particular countries are instructive in throwing into relief how global developments are reconstituted and rendered complex on the ground. When all is said and done it is the people located at different levels and their actions, or inactions and interrelationships that shape higher education.

Higher education has multiple purposes, some relating to the broader global concerns, others dealing with highly localized issues and challenges. At the broader level, the contribution of higher education, research, and innovation to International Relations is increasing in importance and complexity, with the role of higher education in International Relations viewed through a "knowledge diplomacy" lens. Knowledge diplomacy is defined by Knight (in this volume?) as fundamentally different from cultural diplomacy, science diplomacy, and soft power. She identifies eight primary characteristics of knowledge diplomacy, with illustrative case studies from around the world. The examples of knowledge diplomacy focus on how through cooperation, reciprocity, and mutuality of benefits international higher education can strengthen relations between and among countries to address current global issues. Knowledge diplomacy is not, however, without its challenges and demands further reflection and research.

Internationalization of higher education has also found expression through different forms such as student mobility. In recent decades, the number of globally mobile students in higher education has grown rapidly, arguably as a direct outcome of the

increasing commodification of international education. Using Australian higher education as an illustrative case, Rizvi (in this volume) suggests that this commodification is best viewed as involving set of policy processes relating to the ways in which HEIs are now funded and governed. It shows how the commodification of social mobility has thus reconstituted the character of higher education, becoming a site for the formation of an emerging transnational elite class. Globalization and the internationalization of higher education have resulted in greater cross-border student mobility and increased international integration. These developments have influenced the social relations between the locals and the internationals at universities.

Historically, higher education has been an instrument in the battles that have been fought between the East and the West, the South and the North. Chasi (this volume) opines that the perspective of how Global North could bring about development in the Global South is informed by levels of inequalities between the bipolar worlds which are a result of colonialism and the underdevelopment of the South by the North. It assumes the dependency of the South on the North for its development. In this volume the North–South partnerships in the context of higher education internationalization are addressed from the vantage point of the Global South. It reflects on the past, present, and future of North–South engagements in higher education with reference to the notions of colonization, recolonization, and decolonization. A decolonial lens is used to critically reflect on the challenging dynamics of North–South partnerships, particularly regarding continued dependencies and inequalities, and to challenge existing partnerships practices in the broader context of higher education internationalization. Furthermore, it serves as a tool to conceptualize and empower positive change by reimagining North–South partnerships.

As has been noted, this volume is assembled from a Global South perspective that intends to highlight developments in higher education in the Global South in general, and the African perspective. These have not been given attention in the previous editions of this series and therefore make this volume particularly unique. As [Mouhabedai \(2014\)](#) highlights, centers of higher learning have existed in Africa for several centuries, well before the arrival of Europeans. Examples of these are the University of al-Karawiyyin in Fez, Morocco; Al-Azhar University in Cairo, Egypt; and the University of Timbuktu in Mali, the latter being attributed as the oldest in the world. However, modern higher education in Africa has its roots in university colleges that were created by and affiliated with European universities during the colonial period. They were staffed by Europeans or Africans trained in Europe, and their major objective was training the workforce for the public sector and teachers for the rapidly expanding secondary education sector. These institutions were patterned on the European higher education system; and after the colonies achieved independence in the 1960s, the colleges became universities. Because of underfunding that has been associated with the underdevelopment of African countries and former colonies, higher education development in these regions failed to catch up with that in the Global North. However, as some papers in this volume will demonstrate, there have been significant developments in higher education in African albeit not on the same level as those in the Global North, that make a significant contribution to continental development.

The role of higher education in development has been combined with the rate of return on investment both for the public and the individual has contributed to the increased demand for access to higher education. Many countries responded by expansion of higher education provision which led to the massification of higher education. As it will be demonstrated later in this volume, there has been an increase in universal access to higher education over the past two decades in all the regions. Between 2000 and 2018, the global higher education gross enrollment ratio (GER) increased from 19% to 38%. For the same period, the male GER increased from 19% to 36%, while that for females went from 19% to 41%. This demonstrates that women have benefited more from increased access to tertiary education. Currently higher education services 220 million students in 20,000 HEIs globally ([WHED, 2021](#); [World Bank, 2021](#)). Access to higher education can be understood in a diversity of ways, as can the accountabilities that are attached to this notion. The issue of access is addressed in this volume and a distinction between different conceptualizations of access is articulated on how these relate to accountability in the contemporary conditions of higher education, with a focus on university systems, institutions, and practices.

This increased access has not been without challenges but has been characterized by barriers such as poverty, unaffordability because of high tuition fees, entrance examinations, geographical mobility, and discrimination. In this globalized context of numerical student growth, access to higher education is often taken as the opportunity to gain formal entry to a higher education study pathway (Burke this volume). Commonly, this involves a focus on counting bodies of people from social groups that policymakers recognize as historically excluded from participation at tertiary level of their formal education system. Beyond this though, Burke (this volume) argues that if we explicitly move to consider how inequality becomes structured into institutions and practices, the notion of access can also help to explain whose and which knowledge matters in higher education. Drawing on sociological accounts of the character and limits of knowing and knowledge, the term “epistemic access” has been used to explore this dimension of accessibility. Efforts toward “widening” access to higher education before moving to the issue of epistemic access is explored with reference made to the relationship of access to accountability, including the tensions between these terms.

Academic freedom and institutional autonomy receive attention in this volume and the threat they are under. In his paper, Oanda shows how the exercise of academic freedom and social responsibility in African universities has been undermined over time by internal constituencies with the acquiescence of the academics. He further argues that the constriction of spaces for academic freedom seems to be deteriorating more as governments (the traditional inhibitors to academic freedom) have ceded governance oversight to the institutions and legalized staff unions to be part of the governance and management structures of the institutions. On the other hand Hutchens points out that political systems treat academic values differently and the same protections are not afforded globally. In his paper he explores the history of academic freedom and how it is viewed and protected worldwide. Of late, governmental protections have been precarious in some nations and scholars have been reprimanded in countries that encroach onto the autonomy of higher education.

The assault on higher education is not only through a threat to academic freedom but also through the encroaching of market forces in higher education. The paper by Suspitsyna and Pasque examine the current roles of European states, markets, and universities in knowledge production and review the critique of academic entrepreneurialism and neoliberal market influences on European higher education. On the other hand Magalhães and Veiga (this volume) identified the impacts of governance reforms in Portuguese higher education initiated in 2007. Under the influence of the New Public Management perspectives, the changes were driven by the inducement of a quasi-market environment enhancing institutional autonomy and promoting the inter-institutional competition. The reforms have transformed the relationship between the state and higher education system and the power relationships between HEIs' constituencies.

Yonezawa, Shimauchi, and Liu (this volume) examine the transformation of university missions from nation-building and social development, toward global competitiveness and engagement around common global challenges. At universities in East Asia, the translation of knowledge tends to be implemented within a context of hegemonic power, rather than through voluntary academic activities. This paper raises concerns over "losses in translation" that may lead to misunderstandings around the essential characteristics of universities, such as academic freedom and university autonomy.

As part of the pushback on the assault on higher education, Giroux and Filippakou (this volume) argue that the educational force of the wider culture in the age of a raging pandemic, economic populism, and authoritarian nationalism has become a force for promoting a fascist politics, a widespread assault on the welfare state, and a hatred of those groups marginalized by race, class, and religion. At stake here is a further assault on civic culture, civic literacy, and the recognition that a democracy cannot exist without informed, engaged, and critical citizens. They argue that educators, especially those working in higher education, need a new language for thinking about how democracy and politics should provide a new way of thinking about the centrality of critical pedagogy to the production of the ideals of democracy, critical agents, economic equality, and social justice. Their paper concludes by calling for a pedagogy of hope, one infused with a new vision of the future, support for young people who are leading the struggle for economic and social justice, and the widespread adoption of pedagogical practices that will create the agents and the conditions that will enable collective struggles and emancipatory transformative changes.

The use of technology in higher education, digitalization, and green transitions which affect the way we work and learn which have implications for student support and funding of higher education are some of the issues that are explored in this volume. According to Weiland (this volume) digitalization has also meant revision of how information—in journals, books, and other resources—is gained, used, and maintained. For higher education these have given rise to unanticipated forms of roles for scholarly communication, now understood as digital system of exchange of ideas and practices across the many disciplines of inquiry. In this regard, open access, which is another form of the expression of digital transformation, is transforming science and scholarship by removing financial constraints on access to journals and books. The use of technology regarding its impact on curricula is also explored.

A crucial dimension of the globalization and internationalization of higher education has been the neoliberal national, regional, and international contexts within which curriculum change has taken place locally. These have been shaped by what is transpiring within a range of HEIs. We need to know more how men and women in the North and South, and within and across different systems, on a day-to-day basis, receive and work with macro-development and how it articulates with teaching and learning. We suspect that in surprising ways there may be little impact at all. Bologna is not only about "harmonizing" diverse systems, but it also has symbolic meaning for the creation of a more united world in higher education and thus in what is or is not taught in lecture halls and/or online. But none of this is problem-free. Macro-developments such as neoliberal influences are often contested and reconstituted in hybrid ways.

The role and impact of technological development has been far-reaching. The debates about a 4th Industrial Revolution (4IR) pose critical questions about technology and curricula. More specifically, it has redefined, for example, assessment and performance measurements and teaching and learning outcomes and is presently reshaping distance education. These developments have been accelerated by the COVID-19 pandemic. The distinctions between the delivery of online and contact curricula have become blurred in ways which at this point we do not fully grasp.

The massification of higher education is further determining the nature of diversity at universities and colleges and raising more sharply questions about inclusion and equity. Thus, as more students from disadvantaged groups have been included, familiar issues about their alienating experiences within predominant and historically evolved cultures have been posed. How these are evolving should be researched. Questions of differences by race, class, and gender are reproduced within social contexts where countervailing forces pushing groups together. These as we show below are played out in a variety of ways and across diverse settings. They also include and overlap with difference by national origin as a result of recent migrations (Weber and Joubert in this volume).

Global and technological developments provide the background for how young people are prepared for labor markets and the world of work. Familiar concepts such as pathways become relevant in new ways. Thus, for instance, the question is posed about how curricula in schools prepare students for changing workplaces where teamwork driven by the needs for innovation and competition have replaced hierarchy. Men and women, blacks and whites, nationals and recently-arrived internationals must now work together more closely. We focus particularly on the development of professional identities of lecturers in this regard and highlight the importance of the wider social context in which teaching at universities occurs. And here most especially the difference between North and South is evident. For example, in their paper Sichombe et al. (this volume) discuss early career academics and researchers in Namibia require skills and competencies their counterparts in the North take for granted. This determines their struggles to conduct research, publish, and develop networks and thus their professional identities.

Curricula are delivered within overarching national and international contexts. Kenneth Saltman writes that in the United States neoliberalism as economic policy and as ideology has influenced education change from K12 to higher education. What specifically have these restructuring initiatives entailed? The profit motive underpins policy and public debate he says. A critical approach is required to dissecting what is becoming a common language and way of thinking about educational change. In the literature curricula are often abstracted from wider social developments. This volume addresses this problem through this paper. Additionally, what is novel in the analysis by Saltman are the natural and unnatural disasters within the discussions of neoliberalism and globalization. Environmentalism as it relates to curricula is one of the focus areas that regrettably we have neglected.

O'Leary states that research is important in improving higher education pedagogy. His view is informed by longitudinal studies of teachers and students in the UK. These studies as well as the paper by Cook-Sather draw attention to value of qualitative analyses of lecturer-student relations, particularly the emphasis on context and complexity. The existing scholarship highlights multiple difficulties and challenges within pedagogical relations of reciprocity. The compact teachers enter in their engagements with students defines the values, diversity, and specificity of place as key components of the social dimensions of curriculum.

Bajinath, Motala, and Menon show how the idea of a 4IR has been promoted and criticized in recent years. They argue that 4IR lies at the intersections of technological progress, policy, and development, and curricula, and teaching and learning. Against this background and with reference to a middle-income country, South Africa, the paper examines the conditions, challenges, and stumbling blocks that could lie in the way of the implementation of 4IR. But before we talk about implementation the skeptics state, we should examine the previous industrial revolutions and its consequences for the disadvantaged and marginalized. Do we wish more of the same? And what are the implications institutionally in the increased use of digital technology? Mass datasets must be managed and analyzed and this requires the development of institutional capacity. How will the data be used in assessment, for example, and what are the pedagogical implications of e-teaching and e-learning? And the social relations of lecturers and their students discussed earlier? And overall, Bajinath et al. ask, as the critics warn, will another digitalized layer of inequality be grafted onto the inequalities of previous industrial revolutions? History is relevant globally and in the context of historical development in South Africa since the discovery of gold and diamonds in the late 19th century.

Linda van Reyneveld writes that new development in the delivery of teaching and learning programs has been in distance education where the traditional distinction between contact and blended approaches, using technology, is now less clear. The paper poses questions such as: Can we develop frameworks for completely online in distance at residential universities? What will inform and underpin such frameworks and what by way of examples they outline, might these frameworks look like? What institutional changes might be required? The introduction of online distance programs at what used to be traditionally residential places of higher learning raises broader questions about the social relations between teachers and students. The latter as we have seen have been central to curriculum studies in higher education. Shifts toward blended approaches and to online programs, even if confined to distance education at residential universities, have implications for higher education, particularly to the development of curriculum studies.

COVID-19 pandemic has impacted the higher education sector across the globe in unprecedented ways, necessitating a range of extraordinary responses by governments and education institutions, from travel restrictions to campus shutdowns. International travel was negatively impacted with serious implications for international student mobility. HEIs retained students and maintained their access to learning through online courses. Sehoole, Ikwemesim, and Agbaje (this volume) as well as Ayoo (this volume) have examined the higher education landscape in Africa, discussed the key educational processes affected, and how some African higher education systems dealt with pandemic with differential levels of success in sustaining teaching and learning during the pandemic. On the other hand, Global North-based institutions have been able to navigate the pandemic with lesser impact on the delivery of teaching and learning. The ability to introduce and sustain teaching and learning during the pandemic also depended on the level of the use of technological and hybrid methodologies before the dawn of the pandemic.

Ronghuai Huang et al. discuss how the COVID-19 pandemic has highlighted what has been called Online merge Offline (OMO) programs. Based upon hybrid infrastructure, open education merges online and offline teaching and learning. Face-to-face classrooms merge seamlessly in theory with online classrooms. The writers argue that the implementation of OMO should be research-based. This paper is based on four international case studies. The findings draw attention to how the learning environment is constructed, the relevance of technology, communication, and teacher training. They write that the use of technology has limitations. Teachers should reflect on how OMO courses are designed, how they teach, and how learning communities are created and consolidated. Understanding students' experiences and what it means to them is crucial.

A great deal of recent attention has been on the outcomes and assessment in curricula. The paper by Matthew Wawrzynski in this volume focuses on various dimensions of assessment. It is useful he writes to start by trying to define commonly used terms such as assessment and learning outcomes and presenting a step-by-step process whereby the learning process can be determined. This serves as an introduction to the following paper by Dirk Ifenthaler on learning analytics. The adoption of analytics requires institutional change regarding the systemic use of appropriate technology and systems, policy regulations and guidelines, professional training and research (Ifenthaler). The degree of alignment between these factors is likely to be important. Additionally, the importance of changing mindsets and behaviors should not be underestimated and, more broadly, what historically has shaped them.

Learning analytics are illustrative of a broader development in higher education: using performance measurements in assessing learning outcomes. These performance measurements are often digitalized and claim to measure critical thinking which arguably

has been reduced to a competency. The art of reasoning is now called online reasoning. It is against this background that in this volume a call is made by Zlatkin-Troitschanskaia et al. for the critical evaluation methodology of performance measurement. The collection, processing, and analysis of data specific to this field are not problem-free. There is a relevant literature here and future research will be important (Zlatkin-Troitschanskaia et al.). This approach enables us to move beyond mere technical and mechanical implementation of digitalization.

Class size is often viewed as a key determinant of learning outcomes and academic performance. The intricacies of class size make its meaning far from straightforward. It depends, for example, on what one is talking about—the size of a class, the number of students in a program, the incoming cohort? And relatedly who are the constituencies within the university that might have an interest in determining class size? Academics, the budget staff, etc. These are usually the subject of protracted negotiations within institutions and can determine class sizes ultimately decided upon (Okerson in this volume).

Having assessed students, what credits are awarded? The globalization and the internationalization of higher education mean we can interrogate credit validity and recognition beyond national borders. While there have been attempts to synchronize credits across borders, notably, the Bologna Process, most credits are issued locally. Bologna represents a major initiative at the “harmonization” of different, nationally based higher education systems. It is instructive to examine the existing literature and to consider different ways in which cross-border credentializing might be achieved and what problems have arisen (Jason Stone in this volume).

There has been a huge global growth in student numbers in recent times across both the Global North and South. Access to higher education has come to be defined in various ways as write Burke et al. in this volume. These are related to questions about accountability. It has become widespread practice to count the numbers of students and faculty, especially of underrepresented groups and those who have traditionally been excluded from university. This raises broader and more fundamental questions about how inequality becomes embedded in institutions and how it is reproduced. How one defines access can explain what knowledge and whose knowledge is privileged. The idea of “epistemic access” in relation to and in tension with accountability has been used (Burke et al.). This discussion sets the scene for our section on the diversities in higher education.

As higher education has massified, the disadvantaged have been included, but have not always succeeded. Completion rates have been problematic. Conceptualizations of completion have favored students coming from advantaged groups. Comparisons of diverse institutions and systems are also not problem-free and understanding them is important. But despite the concern for completion, what does participation in higher education mean for underrepresented groups? This means focusing attention on the institution and its role in serving what are perceived to be national goals. Those traditional and current interests might not coincide with beliefs and values of the “others” now attending HEIs (Gale and Parker in this volume).

We specifically look at diversity from the position of black women. Venitha Pillay identifies and states her position as a black woman in the South. Women have been included in higher education but remain powerless, she argues. Their exclusion is not overt but embedded in gendered institutional practices and histories. There is a global dimension to this question. Pillay states that white women from the North are more privileged than black women in the South. Being a black woman in academia is compounded by being an academic mother. It is impossible in this context to “balance” life and work. The COVID pandemic has had terrible consequences on women in higher education and on academic mothers. However, there are strategies that can be used to negotiate the subordinate position of women in academia.

It is also useful to focus specifically on individuals at elite universities in a particular country. In Australian higher education students from low-income groups are underrepresented and often the first in their families to attend university. They enter an alienating institutional culture. Gender and class intersect in the stories of two students. Where they come from interacts with where they find themselves and what they wish to become (Stahl and McDonald in this volume).

Pacific minority students have faced difficulties in Aotearoa New Zealand. These challenges regarding the experiences of minoritization, academic performance, and the support or lack thereof can be compared with similar situations in other parts of the world (Cherie Chu-Fuluifaga in this volume). We also therefore focus on the perceptions of learning of adult working-class women students from the North. They were about to transition to the labor market. Their expectations of work and experiences in higher education were classed and gendered. These women experienced the reproduction of inequality (Barbara Merrill and Scott Revers). This volume also unpacks whiteness and building more inclusive cultures. The study by Karkouki draws on case study data at a private institution in the Northeast, United States. The findings can assist academic administrators build diversity and inclusivity.

Historically Black Colleges and Universities in the United States provide an alternative home to the alienating experiences of minority students in predominantly white institutions. The paper in this volume examines the history of these colleges with reference to, for example, the civil rights movement and discusses their unique contribution to US society today. It concludes with notes about their future (Marybeth Gasman).

We wish to draw attention to the many ways in which diversity and student experience can be defined. In the paper by Basit the spotlight is on a minority group of the student population, a particular cohort of students, those enrolled for doctoral study at a university in the United Kingdom. It surveys and analyzes their experiences of teaching, learning, support, and socialization using Bourdieu’s notion of academic habitus. It makes policy recommendations that have implications for future practices.

Pathways are commonly used to understand transitions of young people to the world of work. Harris and Guthrie write that Australian Vocational Education and Training is largely postsecondary and concentrates on lifelong learning and careers. Research highlights the importance of context in the analysis of pathways. They propose recommendations to administrators to better serve student learning in preparations for work. However, as Billet in this volume notes constant change in the workplace means that preparing students for the prescriptions of occupations is not easy. Graduates must translate and adapt what they have learned to the fluidity of the conditions and nature of work and 21st century reskilling.

Bayerlein writes that there are different types of learning outcomes and expectations in a variety of workplaces. This paper explores developments in work in relation to Work-Integrated learning programs. Recently skills in information technology, communication, and the dynamics of working in teams have become important within specific contexts and types of work. Internships have positive impacts and can play significant roles in the future (Bayerlein in this volume).

The growth of the importance of career pathways has become important globally. The paper by Bragg examines the role in the United States of different agencies in programs for youths and adults. It discusses a framework for the evaluation and assessment of career pathways, based on research, including the largest federal investment in career pathways. It concludes with a review of gaps in what is known about career pathways of underserved students.

Erica Smith writes that service-learning is expanding to many countries. It is a type of community-university engagement which is geared toward action-based learning and bridges the divide between on-campus theory and community-based practice with transformative goals. Smith surveys 30 years of competency-based (CBT) in Australian vocational education and training (VET). The goals and content of CBT are criticized as having narrowed over the years. She makes recommendations for improvement.

Against the background of international developments have been concerns regarding student success and demands on poorly equipped lecturers to address these issues. Professional development plays a significant role in teaching and learning despite its systemic neglect. The paper in this volume (Precious Sipuka and Shireen Motala) pays attention to the development of better teachers in South African higher education. It highlights the complexities in constructing and developing lecturers' identities including the impact of social and political contexts. Thus, alternative approaches to professional development in higher education are suggested. The study by Sichombe et al. examined the experiences, career development, and difficulties encountered by early career researchers in Namibia, a developing country located in the South. The study found that early career academics needed mentorship and guidance in research methods, project development and implementation, writing, networking, collaboration, and publications. There was a gap between experienced researchers and their younger colleagues that must be narrowed through closer collaboration with senior and more experienced academics.

In conclusion, the papers in the volume have demonstrated the crucial importance of viewing shifts in higher education policy and practice from the perspective of the histories, cultures, and experiences of and the diversities within various societies. They have shown how the focus on the developments within the Global South is of special significance. They have pointed to the need to understand the world of higher education more from the realities, individuals, and constituencies on the ground and to use them as the point of departure for the construction of further theoretical perspectives. The growing scholarship on postcolonialism has problematized representations of the South from the point of view of the North (see Weber and Joubert in this volume). The implications for future research, including issues related to research methodologies, are crucial and wide-ranging and have the potential to redefine the field of higher education.

DEVELOPMENTS IN HIGHER EDUCATION

Higher education strategy formations in shifting landscape of higher education <i>Meltem Akbulut Yıldırım, Serap Emil, and Fatma Nevra Seggie</i>	1
Knowledge production in Europe: actors, policies and critiques <i>Tatiana Suspitsyna and Penny A Pasque</i>	12
Transformation of university missions—from nation-building to a focus on common global challenges reflections from East Asia, under the risk of being “lost in translation” <i>Akiyoshi Yonezawa, Sae Shimauchi, and Jing Liu</i>	21
Economic impact of higher education on students, corporations and society <i>Peter Arena, Tim Carroll, Suzanne Lyons, and Liang Zhang</i>	29
Academic capitalism and market thinking in higher education <i>Oliver Wieczorek and Richard Muench</i>	37
“Reschooling” higher education: the dynamics of curriculum in South Africa <i>Kirti Menon and Gloria Castrillón</i>	48
New pathways in education <i>Dieter Dohmen</i>	57
Open access and the unfinished transformation of scholarly communications <i>Steven Weiland</i>	63
Innovations in university student learning research into blended course designs: incorporating self-report and observational data <i>Robert A Ellis, Feifei Han, and Ana-Maria Bliuc</i>	74

Uses of technology in navigating the pandemic: the case of African higher education: Chika Schoole, Lydia Ikwuemesim, Olaide Agbashe <i>Chika Schoole, Lydia Ikwuemesim, and Olaide Agbashe</i>	83
The impact of COVID-19 on higher education in Africa <i>Philip O Ayoo</i>	91
Issues of production and utilization of knowledge: multiple uses of knowledge <i>Azeb Tadesse, Bri Damacio, Kiana Billot-Vasquez, and Walter R Allen</i>	102
Regimes of research and development funding in higher education <i>Bailey A Brown</i>	108
The hollowing out of academic freedom from African universities; from external capture to internal implosion <i>Ibrahim Ogachi Oanda</i>	114
The changing functions of libraries in higher education <i>Sarah R Fitzgerald and Jennifer M Eustis</i>	124
Uses and abuses of social media in higher education <i>Lillian Vega Castaneda and Mario E Castaneda</i>	131

POLICY, GOVERNANCE AND LEADERSHIP

Higher education, critical pedagogy, and the challenge of resistance <i>Henry A Giroux and Ourania Filippakou</i>	139
About the rise, the characteristics and future of New Public Management in Higher Education <i>Bruno Broucker</i>	145
Governance, institutional autonomy and leadership in Portuguese higher education <i>António Magalhães and Amélia Veiga</i>	152
Publish or perish <i>Hanne Andersen</i>	158
Internationalization in English? Problematizing the role of language in higher education internationalization <i>Johanna Ennser-Kananen and Taina Saarinen</i>	167
Academic freedom protections in national and international law <i>Neal H Hutchens, Macey L Edmondson, and Frank J Fernandez</i>	174
The funding of higher education: international perspectives <i>Ben Jongbloed</i>	183
Faculty compensation and salary equity <i>Linda Serra Hagedorn PHD</i>	191

INTERNATIONALISATION

Knowledge diplomacy: the role of international higher education, research and innovation in international relations. <i>Jane Knight</i>	202
North–South partnerships in higher education <i>Samia Chasi</i>	210

Reimagining internationalization of the curriculum <i>Betty R Leask</i>	220
International higher education and the commodification of student mobility <i>Fazal Rizvi</i>	233
Postcolonialism in the movies and higher education: a case study of the narratives of South African and international students at the University of Pretoria <i>Everard Weber and Venise Joubert</i>	241
CURRICULUM, TEACHING AND LEARNING	
Neoliberal education: from capitalizing on disaster to critical pedagogy <i>Kenneth J Saltman</i>	250
Linking research and teaching to benefit student learning in higher education: complexity, collaboration and a tailored approach <i>Matt O'Leary</i>	258
Reciprocal teaching and learning through student-faculty pedagogical partnership <i>Alison Cook-Sather</i>	268
Implications of the Fourth Industrial Revolution in the vortex of higher education in South Africa <i>Narend Baijnath, Shireen Motala, and Kirti Menon</i>	279
Toward a framework for the implementation of fully online distance education at a residential higher education institution <i>Linda van Ryneveld</i>	287
Design of Online-Merge-Offline (OMO) learning environments in the post-COVID-19 era: case study analysis <i>Ronghuai Huang, Muhammad Yasir Mustafa, Ahmed Tlili, Rongxia Zhuang, TingWen Chang, and Daniel Burgos</i>	296
Assessing student learning outcomes <i>Matthew R Wawrzynski</i>	305
Advantages and challenges of performance assessment of student learning in higher education <i>Olga Zlatkin-Troitschanskaia, Jennifer Fischer, Henry I Braun, and Richard J Shavelson</i>	312
Adoption of learning analytics <i>Dirk Ifenthaler</i>	331
The intricacies of class size in higher education <i>Justine R Okerson</i>	336
Credit for experience, credit recognition and transfer <i>Jason E Stone</i>	343
The disruption of Black history and critical pedagogy in international higher education curriculum <i>Miriam Chitiga, Kolawole Samuel Adeyemo, and Carmen Wade</i>	350
Non-completion amongst black working-class students in South African universities: the dangers of a single story <i>Mukovhe Masutha</i>	356

DIVERSITY, INCLUSION, AND EQUITY

Tensions in access and accountability <i>Penny Jane Burke, Matthew Bunn, and Matt Lumb</i>	367
The problem with higher education student completions in the global north <i>Trevor Gale and Stephen Parker</i>	374
Women in higher education: exclusion, inclusion and seclusion <i>Venitha Pillay</i>	381
The first-in-family experience: gendered and classed subjectivities in elite higher education <i>Garth Stahl and Sarah McDonald</i>	392
Minority learners, diversity, and educational outcomes: the case of Aotearoa, New Zealand <i>Cherie Chu-Fuluiifaga</i>	398
Experiencing class and gender: mature women students and their journeys from HE to the labor market <i>Barbara Merrill and Scott Revers</i>	406

Introduction

Universities being one of the oldest and resilient institutions have been continuously evolving with the developments and turning points of each era in the history (Scott, 2006; Young and Pinherio, 2022). There have been some changes moving institutions forward, while there are some developments limiting the capacity of higher education. Thus, it is almost urgent to examine the nature of the shift in the higher education landscape to characterize the strategy formation in today's world. The core functions of higher education have become convoluted due to rankings, grants, measurable performance indicators, business management perspectives, and most importantly, its contribution to economic development. On the one hand, higher education institutions (HEIs) are still responsible for producing scientific knowledge, educating students, and serving the community to uphold their core functions. On the other hand, glancing over the strategy formation with a critical eye, it is seen that worldwide competition fetish is existent in higher education systems directed by the shamans—macro or micro actors—as Naidoo (2018) defined. These actors are governments, international organizations, or political actors with the agenda of harsh competition for HEIs (Naidoo, 2018). Yet, we strongly agree with UNESCO Assistant Director-General for Education Stefania Giannini's statement from the most recent UNESCO World Higher Education Conference 2022: "competition is important when it is about improving our institution, but it is not about putting in the rankings and having a competitive approach to the common public good" (O'Malley and Warden, 2022, para. 18).

Framed from this perspective, our argument creates possibilities of thinking about the conventional wisdom that universities strive for the truth, and that's their *raison d'être*. What is gaining ground, though, is that the characteristics of today's strategy-making have put them on a trajectory wherein they are becoming estranged from their criticality in the search for and production of truth. The intricacy of this issue lies in its direct bearing on how HEIs reestablish their core functions while living at the heart of and growing out of a variety of social, political, cultural, and economic factors. With this in mind, we analyze how higher education strategy formation processes operate in the higher education landscape and their implications on the criticality of HEIs in the search for and production of truth through cross-regional triangulation of strategy development practices. Based on these lines of analytical framing, in what follows, we first present the background of our argument by examining the nature, scope, and scale of the trends that operate in the formation of higher education strategies. Second, we discuss the nexus between these trends and the essence of the modern university before suggesting the study of the essence of the modern university as a mode of analysis for future research.

Trends in the higher education strategy formation

The central question driving our literature review is twofold: where, why, and how strategies originate in higher education and who is involved? We conduct this inquiry from the standpoint that calls into question the essence of the modern university. We aim to explore the existing complexities and countervailing patterns that shape the higher education strategy formation processes. To this end, in the remainder of this section, we unfold in broad terms the relationship between higher education and economic growth and consider in more operational terms how strategy formation in higher education manifests itself across the world.

Strategy formation as a double-edged process: two perspectives

Strategy, traditionally defined as explicit, intentionally developed in advance of specific decisions, is a set of guidelines determining the action of a given institution. It is crucial to note that strategies can be *a priori* or *a posteriori* affecting decision-making (Mintzberg, 1978). Yet, the strategy formation in today's world is not a straightforward process, for the nature of HEIs is multi-layered and complex. Resilience in universities (Young and Pinherio, 2022) allows HEIs to protect their essential function and identity while they are engaged in these complex and ever evolving change initiatives in relation to external forces. This is a rather chaotic process

where the pressure of external forces is challenged by the fundamental characteristics of the university that have been shaped throughout history.

These external forces attributed to HEIs, such as being entrepreneurial and innovative or producing high employability and reputation, are bound to complicate how to reinscribe the role of the university in societies. Some of the underlying factors for these trends can be stated as globalization, knowledge economy, or internationalization, though, in essence, it is the link between economic growth and education, as claimed by many. Accordingly, based on the extant literature, two main perspectives are at issue in the debate over higher education (Schwartzman, 2020). One of them—mentioned above—can be called from an economic perspective focusing on economic development around the globe. The other one focuses on education—the true essence of the university—“complex processes of social transformation and institutionalization” (Schwartzman, 2020, p. 10). In order to contextualize some of the practices adopted in the higher education strategy formation process that we explore in the second part of this section, we now attempt an overview of these two perspectives.

The economically oriented perspective, which has received sustained attention from economists and international agencies, analyzes higher education in terms of its possible contribution to economic growth and development. There are different ways HEIs can contribute to this perspective through research and technological innovations and through teaching graduates with capabilities for employment and to increase productivity (Oketch et al., 2014). There is also the human capital theory dominating the discussion on higher education outcomes since the 1960s (Marginson, 2017). By general agreement, Shultz (1963) and (Becker, 1993) mark the inauguration of a renewed interest in education as an investment in capital, encouraging the development of an economic orientation toward higher education in the 1960s and ensuing decades. This human capital theory, with its focus on “activities that influence future monetary and psychic income by increasing the resources in people” (Becker, 1993, p. 11), has had a substantial impact on education and economic growth relationship, more so on higher education with the advent of mass higher education in the 1960s, along with some suspicions on the concept of the academy (e.g., Becker, 1993) reaching to the present day (e.g., Scott et al., 2017). Education and training were considered the most essential investment in human capital (Drucker, 1993) which also is defined as the economic approach to human behavior (Becker, 1993) assuming an educational policy consensus (Lauder et al., 2006, pp. 8–10). The link between education and development for developing countries is strongly advocated (Ayers, 2000) and the human capital theory, within this context, becomes instrumental (Eide and Showalter, 2010; Oliver, 2004).

Birnbaum (1999), however, criticizes that there is little evidence to support this view (see also Enders, 2010) and stresses the importance of a collective initiative of higher education leaders in reorienting discussions about the purposes of higher education. According to him, developing new narratives or revitalizing the old ones demands connecting to the public. This point of view is not far removed from the suggestions in critical education policy scholarship. For example, Ozga and Lingard (2007) suggest the creation of research communities to resist the centrality of the all-pervasive “research steering” in knowledge production (pp. 78–79). Rizvi (2006) makes a plea to researchers to collectively “develop an alternative educational policy agenda,” “an alternative social imaginary committed to strong democracy and global justice” (p. 203) against the narrative supremacy of the “neo-liberal imaginary” (p. 200). According to him, the processes of (1) international cooperation, (2) global circulation of ideas, (3) international conventions, and (4) coercive strategies (pp. 201–204) work in collaboration to feed neo-liberal policies, attributing transnational, international, and global dimensions to national educational policies. As researchers, in his view, we need to analyze these processes to understand how to locate local and national educational policies within this multidimensional approach to education. Various reconfigurations of these processes and hence diffusion of authority at all levels are evident in the landscape of higher education strategy making today. Examples of current processes are discussed in the second part.

In the second perspective, education is sociological in orientation and approaches the role higher education plays in societies from the vantage point of its relation to social transformations, its educational and socially progressive prospects rather than from the restricted domain of economic development. Higher education, in its many varieties—private institutions, universities, vocational schools, and similar bodies—is perforce in the borderlands between being perceived as a credentialing endeavor and being admired as a stronghold of the intellectual progression by societies with which they evolve in tandem. Even as it has taken various institutional forms since the foundation of the first modern university in 1088, the University of Bologna, this chasm—if such it is—is still kept alive for the most part by the complexities ingrained in this long historical process of bridging relations with wider society (see also Rüegg, 2004). In 1983, a pioneering work by Burton Clark casted some light on the connections between higher education systems and change, while on the other hand, it has encouraged further exploration of the governance of higher education (e.g., Salazar and Leihy, 2013). As Lang (2017) argues, one can also use Clark’s Triangle of Coordination including three forces—“state authority,” “academic oligarchy,” and “market” (Clark, 1983, p. 143)—as a comparative tool for understanding institutional change within a system compared to other systems.

A crucial moment in understanding the links between higher education and social transformations came in 1988 with the Magna Charta Universitatum. The Magna Charta, endorsed then by 400 representatives from around the world, stands as the first universally accepted charter of the university as an institution. Acknowledging the challenge of conciliating the views of institutions with diverse geographies, histories, and cultures, Stephen Lay, in his *The Interpretation of the Magna Charta Universitatum and its Principles*, suggests adding a civic role to the principles of the Magna Charta to guide the university administration (Lay, 2004, pp. 107–111). In his view, this is a vital task of the university to get a foothold in the deep-seated challenge of engaging with society given the transformations such as globalization, knowledge economy/society, internationalization, and the like (Lay, 2004).

The Magna Charta Universitatum has recently been reviewed to sustain the positive contribution of higher education to social transformations. As of October 18, 2021, 339 out of 947 universities from 65 countries have signed the new version of the Magna

Charta. While remaining committed to its original fundamental principles—institutional autonomy, freedom of inquiry, and indivisibility of teaching and research—the Magna Charta Universitatum 2020 now includes a clear statement on the civic role and responsibility of the university under “Principles, Values and Responsibilities” as follows:

Universities have a civic role and responsibility. They are part of global, collegial networks of scientific enquiry and scholarship, building on shared bodies of knowledge and contributing to their further development. They also are embedded in local cultures and crucially relevant to their future and enrichment. While they are immersed in and connected with global developments, they engage fully with and assume leading roles in local communities and ecosystems (p. 2).

Supporting this civic role of higher education, Paul Ashwin, in his recently published book, *Transforming University Education: A Manifesto*, exactly pulls the audience’s attention from higher education as a commodity to an institution contributing to the development of students from an educational sciences perspective. He rebukes the dominant narrative as economic arguments and invites us to revisit the role of the university in transforming the students’ lives (Ashwin, 2020). He, then, elaborates the purpose of university education as student development through the transformational relationship with disciplinary or professional knowledge.

What the prospects might be going forward with these educational perspectives remain yet to be seen. One can argue that the unfolding of the two perspectives on higher education points to a double-edged relationship between higher education and economic growth which looms large in the modern university strategy formation, complicating the roles of the university and charging them with a diverse set of tasks. Perhaps what is declared under Values, Principles, and Responsibilities in the Magna Charta is a call to galvanize support for proactive ownership so that we can cut a familiar path across.

Strategy formation across world regions

To comprehend higher education in the modern world, examining the national, international, (bi-) regional, and transnational networks or associations would allow scholars to reframe the strategies for HEIs. To this end, this section provides examples of the trends in higher education strategy-making from five world regions and also inter-regional agencies in no particular order, while imperfect, following the UN designations: Africa, Americas, Asia, Europe, and Oceania.

Higher education in North America is closely linked up with the North American Free Trade Agreement (NAFTA), now known as the United States-Mexico-Canada Trade Agreement (USMCA). NAFTA, signed between Canada, Mexico, and the United States in 1992, came into effect in 1994. The trilateral trade agreement created a free trade and investment region among the three countries of North America through the elimination of most tariffs on products and also aspired to protect intellectual property rights and to foster fair competition (SICE the OAS Foreign Trade Information System, 2021). In 2020, three member countries accounted for 28% of the world’s gross domestic product (GDP), with a combined GDP of US\$23,6 trillion and a combined population of more than 496 million peoples (The World Bank and World Development Indicators, 2020a,b). Within the context of higher education, the three-country accord aimed to play a bridging role not only in stimulating cross-border academic collaboration, cooperation, and exchange, but also in eliminating obstacles to such cooperation and exchange via a joint leadership of the three countries. To this end, a Trilateral Steering Committee (TSC) was established in 1991 to guide the regional cooperation process in higher education (Mallea et al., 1997). Another ripple effect of NAFTA is the development of trilateral associations such as the Consortium for North American Higher Education Collaboration (CONAHEC) and the North American Institute (NAMI). Illustratively, CONAHEC, established in 1994, seeks to advance the human capital formation in the North American region and currently has around 180 members. While NAFTA partners form its core membership, institutions from around the world may also join the network based on the defined criteria. Among its activities are organizing conferences, coordinating academic exchange and mobility programs, helping members build international partnerships as their liaison, and publishing on matters of concern.

Barrow et al. (2003) argue that the TSC, CONAHEC, and NAMI are indicative of the institutionalization of NAFTA’s economic orientation toward higher education. In their view, economic concerns of the deal such as workforce development and building global competitive advantage over the European Union, Asia, Japan, and Australia through, say, technology transfer and flow of academics and students across the region have gained ground in the region thanks to the efforts of these three institutions while efforts targeted at spurring inter-cultural exchange has remained to a large extent meager. That economic concern is also evident in the 2000 report of the three national associations of universities—The American Council on Education (ACE); la Asociación Nacional de Universidades e Instituciones de Educación Superior [the National Association of Universities and Institutions of Higher Education] (ANUIES); the Association of Universities and Colleges of Canada (AUCC) (renamed itself as Universities Canada in 2015).

The report, *Increasing North American Higher Education Cooperation, Collaboration, and Exchange Through a Trilateral Education “Marketplace,”* prepared with support from their respective governments and submitted to the Trilateral Steering Committee, defines “a virtual marketplace” for higher education, goal of which is “to serve as ‘one-stop shopping’ for North American institutions interested in collaboration and exchange in higher education” (Collins, 2000a, p. 1, emphasis in original). For, “a virtual marketplace” is “the most cost-effective, productive, and sustainable approach to fostering North American interchange” (Collins, 2000b, p. 3). Consequently, it can be argued that, in the years since NAFTA, higher education’s relation to the Northern American region has mostly evolved from an instrumental lens. NAFTA was restructured recently and, building on NAFTA, the new United

States-Mexico-Canada Trade Agreement (USMCA) took effect on July 1, 2020. The ripple effects of the renewed deal remain to be seen, yet the emerging documents, with their economic argument relying on higher education for workforce, skills, and technology development, point toward a continuation of the market-based strategy-making trend in higher education within the USMCA frame (e.g., Santos and Wilson, 2021).

Australia and New Zealand, on the other hand, carry an outsized weight in higher education strategy formation in Oceania. Besides geographic isolation that impacts the policy settings of all the Oceanian countries, demographic disadvantages, low affordability, often poor education quality and educational facilities at all levels, lack of employment opportunities, threats of natural disasters, and dependencies on certain sectors—fisheries, agriculture, and tourism—form policy fundamentals within other Oceanian countries according to the 2021 *UNESCO Science Report* (Scott-Kemmis et al., 2021, pp. 707–708). To address these pressing policy issues, the Pacific Islands Forum, one of the ten intergovernmental organizations constituting the Council of Regional Organizations of the Pacific (CROP) and the body focused on economic and political concerns, endorsed the Framework for Pacific Regionalism in 2014 with its 18 members including Australia and New Zealand (Pacific Islands Forum Secretariat, 2014).

Yet, whether the implementation of the Framework has been effective is highly contested in the context of higher education. For instance, the 2021 *UNESCO Science Report* highlights that no legal guidelines for research exist in about half of Pacific Island countries and projects a continuity in limited budget allocation to research capacity building in many Pacific Island countries (Scott-Kemmis et al., 2021, p. 708). In line with this finding, Jacob et al. (2018) argue underdeveloped higher education opportunities as one of the root causes of migration from these Oceanian countries to Australia and New Zealand. Furthermore, Asia as a region of interest weighs heavy on the policy agendas of both Australia and New Zealand. The signing of the Regional Comprehensive Economic Partnership (RCEP) between the ten member states of the Association of Southeast Asian Nations (ASEAN) (Brunei, Cambodia, Indonesia, Laos, Malaysia, Myanmar, the Philippines, Singapore, Thailand, Vietnam) and its five free trade agreement (FTA) partners (Australia, China, Japan, New Zealand, and Republic of Korea) on November 15, 2020 connects about 30% of the world's population and GDP, forming one of the world's largest free-trade pacts. Whether the new agreement will enhance the existing disparities in higher education in Oceania will hinge on how both nations balance the implementation of RCEP and the Framework for Pacific Regionalism. Nonetheless, the recent research hints at the possibility of increasing the incentives for Asia engagement.

To exemplify, a key higher education strategy development trend in Australia concerns how to navigate higher education reform in light of the rise of Asia in the region and beyond. The Australian Government's White Paper, *Australia in the Asian Century*, is the most recent comprehensive report elucidating Australia's Asia engagement vision and the ways in which Australia's geographic location and connectivity with Asia affect Australia's future prosperity in the strategically contested Indo-Pacific region (Australian Government, 2012). Accordingly, the report situates this shift of power to the region as fundamental to Australia's policymaking and provides an account of how to build Asia-relevant capabilities. Placing higher education among strategic areas in Australia's vision of Asia engagement, the report suggests "every Australian university to have a presence in Asia" (p. 174) through, for example, encouraging in-Asia study by Australian students; developing partnerships and exchange arrangements; and encouraging the take-up of Asian studies and some priority Asian languages, such as Chinese, Japanese, and Indonesian, by improving the curriculum and pedagogy (pp. 171–175). At this point, however, it is worth noting that regardless of the appeals of the Australian government to the whole of Australia to increase Asia proficiency, deficiency of Asia capabilities is still a salient policymaking challenge in all sectors of Australia (e.g., Henry, 2016; Department of the Prime Minister and Cabinet, 2019). Henry (2016) points to the narrow lens of international competitiveness as to why Australia has continued to underinvest in Asian capabilities. As an example, Rizvi (2021), based on the perceptions of Chinese and Indian students in Australia, argues that a market-oriented strategy-making in universities leaves higher education in the human capital formation conundrum, subordinating the exchanges among students and formation of transborder communities. Hence, one can conclude that as higher education in Australia and New Zealand are disproportionately far ahead in the structuring and distribution of capabilities and power, the strategy development processes of the two countries are more likely to steer the course of the functioning of higher education in Oceania.

Regional partnerships are of strategic importance in higher education in Europe. The Bologna Process, which came into effect in 1999 with a targeted initiative to create a common higher education area and market—the European Higher Education Area (EHEA)—by 2010, is a notable example in this regard. Viewed from this perspective, inter-regionalism in European higher education strategy formation functions as a "strategically selective terrain," "bypassing existing scalar fixes, such as those of the nation state and its Westphalian claim to territory and sovereignty" (Robertson, 2010, p. 34). The EHEA operates today in 49 countries reaching far beyond the European Union (EU) member states and is a voluntary international exercise involving the European Commission as a member, yet being party to the European Cultural Convention is a precondition for the EHEA membership. A thorny question about this interregional agreement is the extent to which a voluntary approach benefits the implementation of the objectives set out by the EHEA Bologna Process, for progress to this end is slow and requires the development of new strategies (Zgaga, 2020). According to Bergan (2015), a perceived decline of political interest is likely to explain the low engagement on the side of the EHEA stakeholders. Indeed, what seems to be high on the political agenda of European leaders are two other regional initiatives—the European Universities Initiative and the European Education Area (EEA).

The European Universities Initiative is an emergent flagship initiative developed to build an EEA limited to EU member states. A close look into the strategy-making processes of these initiatives might serve to glean the Union's role within the context of higher education. In the March 2017 *White Paper*, the European Commission positioned education policies as critical to Europe's competitiveness and resilience at a global scale (European Commission, 2017a). In the *Strengthening European Identity through Education* report presented to European leaders in the November 2017 Gothenburg Summit, the Commission with a vision to build

a European Education Area (EEA) by 2025 recommended the building of “world-class European Universities” (European Commission, 2017b, p. 11). As a follow-up, in the December 2017 Conclusions of the Gothenburg Summit, European leaders set an objective to create “some twenty ‘European Universities’” by 2024 (European Council, 2017, p. 3, emphasis in original). In response, the Commission co-developed the concept of European Universities with HEIs, students, and member states as “ambitious transnational alliances of higher education institutions developing long-term structural and strategic cooperation” (European Commission, 2019, p. 1). To date, 41 European University alliances have been selected. The fact of the matter is that the idea of a European university is a source of deep-seated discussion, as also pointed out by Gunn (2020), and it still is not clear how well the Europeanization-inspired reforms speak to the national contexts.

Beyond the EU as a regional global actor, there are numerous national/international associations of universities within Europe. And some are relevant players not only in negotiating interests in strategy-making but also in turning strategies into policies through regions. In this respect, four illustrative examples are the European Association of Institutions in Higher Education (EURASHE), European University Association (EUA), Association of the Carpathian Region Universities (ACRU), and Universities UK (UUK).

Founded in 1990, EURASHE currently represents 67 HEIs of every type and size from 40 countries within and beyond the EHEA. Mainly concerned with issues related to professional higher education and positioned to build strategic alliances between HEIs and the labor market, the Association undertakes activities, including policy development, participation in joint research projects, organization of conferences and networking events, and advocacy of members’ interests in their relations with European and national policymakers. It works closely with other stakeholders in the EHEA, pursues the development of the EHEA and the European Research Area (ERA), and its membership is open to those who can commit to the EURASHE policy principles and promote the EURASHE working agenda that accepts the EHEA framework. Another example of comprehensive associations of HEIs with policy-influencing powers is EUA, whose members are individual European universities of any type, national associations of universities, university alliances, national rectors’ conferences, and institutions with common interests. Founded in 2001, the Association represents more than 850 members from 48 European countries in, like EURASHE, various policy settings such as European institutions, the Bologna Process, and the Council of Europe. It also engages in activities similar to those of EURASHE, is in support of the European Universities Initiative, and operates within the EHEA framework. Different from EURASHE and EUA, The Association of Carpathian Region Universities.

(ACRU) is more of an intra-regional association of universities. Established in 1994, the Association comprises six countries of the Carpathian region across East-Central Europe—Hungary, Poland, Romania, Serbia, Slovakia, and Ukraine—and now has 23 members (one from Hungary, one from Serbia, two from Slovakia, four from Poland, seven from Romania, eight from Ukraine). Any university beyond the Carpathian region may join its membership whose composition involves associate and cooperating partners from Prague, the United States, and the United Kingdom. ACRU is distinctive in that it seeks to promote the development of the Carpathian region and its cultures and languages through, for example, academic mobility, forums and workshops, and cooperation with local authorities and nongovernmental organizations (NGOs). UUK, on the other hand, is representative of a comprehensive national university association with international standing. Established at the meeting of 22 university leaders in 1918, UUK now represents 140 universities across the UK Universities Wales and Universities Scotland are part of UUK and autonomous in their operations. The Association contributes to the issues such as quality, funding, research and innovation, and internationalization through the Universities UK International (UUKI) team. Its core activities are raising the profile of the universities, providing guidance, influencing policy decisions through political advocacy, and advancing UK higher education at all levels.

In addition to the well-established higher education systems examined above, there are numerous associations and cooperation, including the universities in other continents. For instance, in Latin America and Caribbean higher education, the World Bank report from 1997 highlighted the importance of HEIs not only for economic developments but also for promoting democracy and space for critical thinking (de Moura Castro and Levy, 1997). The institutions in the region back then were reported as changing too little or too slowly while they were struggling with meeting the needs of students or the job market. Coming into 2000s, the increasing student enrollment in line with national economic restructuring was observed (Holm-Nielsen et al., 2004). They stated that similar to Africa, the Latin American and Caribbean countries have experienced a higher demand for higher education in the 21st century and been challenged by the restrained resources. Between 1985 and 2002, the development of private higher education has been observed in numerous countries like Brazil, Chile, Colombia, Peru and El Salvador, Argentina and so on (Holm-Nielsen et al., 2004).

The Latin American and Caribbean universities, gathered, for example, under the Association of Universities of Latin America (UDUAL) established in 1949, and the Caribbean was added later in 2004. They support academic exchange, mobility, recognition, and transferability and ensuring the quality of higher education. The mission of the association is “to drive academic and public politics that encourage the higher education institutes’ essential activities, considering their key connection with different regional realities, in order to be a strategic factor in the sustainable, democratic and inclusive development” (UDUAL, n.d., p. 4). UDUAL being the largest network of the HEIs in the region positions itself as the interlocutor between HEIs, governments, and society. Different from the other bodies mentioned above, it aims to facilitate an effective dialog for public politics. Even though the similar trends such as international cooperation, or HEI transversal perspectives drive the actions of the association, they tend to concentrate on some core issues—interculturality, gender equality, online education, digital society—linked with each university in their network. It is also important to note that they defend the university autonomy and freedom in academic, research, and institutional management. Some of the strategic projects of UDUAL are The Council for International Assessment and Accreditation (CEAI in Spanish); The Academic Program of Student Mobility (PAME in Spanish); The Common Space for Online Higher Education (ECE-SELL, in Spanish); Master’s Degrees, Massive Open Online Courses (MOOCs) and certification courses.

As a result of the Alfa PUENTES project, beginning from 2011, The Latin American Higher Education Area collaborated with European and Latin American University Associations by a bi-regional management team. A total of six European Associations and 14 Latin American university associations came together to deepen and widen the internationalization of higher education. The joint activities among the universities from Latin America and Europe worked toward quality assurance, transferability of degrees, and academic mobility (Kind and Colucci, 2014).

As an example of the economic argument, we can take a look at the Asian Development Bank report (2011), which presented the issues and strategies for Asian universities. The main roles of the HEIs mostly circle around the need for technical and administrative personnel in addition to its services as the incubator of innovation. The report involves target countries (Cambodia, Lao PDR, Mongolia, Viet Nam, Indonesia, Malaysia, Philippines, Sri Lanka, Thailand, India, and PRC) and the reference economies (Hong Kong, China, Singapore, Japan, and Republic of Korea). The challenges are defined more in line with the rest of the world, such as increasing enrollment, demand for research, and financial limitations over and above the decline in HE quality. The resolutions to these pressures are grouped within five areas as internal efficiency, external efficiency, cost and financing, administration and governance, finally access and equity that covers all the existing issues of higher education. However, the report states that the biggest needs in higher education are less capital intensive and more about the university leaders, faculty members, and national and institutional level policies with greater collaboration among those.

ASEAN, the Association of Southeast Asian Nations, with 10 member states formed in 1967 in Thailand, is an important regional cooperation to have an impact on economic growth, social progress and cultural development. While all aspects of economic, political, and socio-cultural development are considered by the association, higher education is also given particular attention. One of the key documents, ASEAN Declaration on Higher Education (n.d.), defines higher education as the catalyst of development through the following principles. Higher education being accountable for higher quality contributes to the wealth and well-being of people through synergy created among governments, industry, community, and academia. It also fosters entrepreneurial endeavors, mobilities, and visibility of the academic community in the global arena. Finally, in the declaration, higher education is given the responsibility of supporting sustainable development via its curriculum, research, community service, and stakeholder engagement.

Asian Universities Alliance (AUA)—a higher education body—was formed with 15 universities in 2016 by the proposal of Tsinghua University for the purpose of student mobility, research collaboration, strategy and policy and annual evaluation of Asian higher education. These works were designed around three themes—Artificial Intelligence & Data Science, Asian Civilizations, and Energy & Sustainability—representing the regional and global challenges. The AUA aims to be the platform for the “innovative collaboration ecosystem” among academia, government, and industry. Another body called Association of Asian Universities was established in 2013 with 29 universities from 8 countries. Similar to the AUA, this association lands itself into the creation of the joint Asian educational space, which focuses mostly on diversity and internationalization aspects of higher education. Thus, it regards the exchange and mobility programs among the member universities. Association of Universities of Asia and the Pacific (AUAP), on the other hand, is the oldest union established in 1995 initiated by the Suranaree University of Technology, Thailand. The main mission is similar to the others, promoting the culture of quality, innovation, and research in the Asia and the Pacific region. With the widest network with 161 member universities, the AUAP have been focusing on student and faculty mobility, faculty professional development, internationalization, global leadership through which they intend to learn and share the best practices with other universities.

Looking at the African continent, we see the Association of African Universities (AAU), located in Ghana, has been defined as “a platform for research, reflection, consultation, debates, cooperation, and collaboration on issues pertaining to higher education” (AAU, 2021, para. 4). It was formed by 34 public universities in 1967 in Rabat and has 320 members now. The Association aims to increase the quality of higher education in Africa and build networks among member institutions. Looking at their strategic goals, it advocates for an effective voice in national, regional and international levels. Ensuring the quality of HEIs in Africa seems to be the main focus, yet there are not many details on how or guidelines provided as a roadmap. Fredua-Kwarteng (2020), on the other hand, specifically discusses the strategic planning work in African higher education systems stating that the national context is necessary to consider even though strategic plans are answers to the challenges in the external environment. He raises an important question for African higher education as “How is strategy for an institution conceptualized or perceived in the African cultural context?” (Fredua-Kwarteng, 2020, p. xx).

Dei et al. (2019) utilized the philosophical approach of methodic doubt to examine the challenges and opportunities of African universities in the 21st century. Similar to any other higher education system, tertiary institutions are in the center for the development of Africa’s human capital and the enhancement of the African identity. As a result of the long history of colonialism, the dominance of the western model of higher education (Teferri and Altbach, 2004), Dei et al. (2019) state that the western philosophies of education can be blended with the indigenous education system. However, there are doubts about this in terms of African higher education producing its own knowledge systems to be able to compensate for the effects of colonialism.

Latin America, together with Africa, are the two continents identified as having the fewest top quality research-intensive universities in accordance with the world university rankings (Altbach and Salmi, 2021). This, by itself, may be seen as the basis of new innovative practices in HEIs in these regions. Looking at the suggestions made by Altbach and Salmi (2021), the second Cordoba reform is hoped to bring the Latin American universities’ level to the World-class universities. Increased public funding aligned with accountability, commitment to national and social development, modern governance systems, less student population, interdisciplinary and international dimensions to the university systems are some of those suggestions to increase the number of top research-intensive universities (Altbach and Salmi, 2021).

The multinational bloc—BRICS (Brazil, Russia, India, China, and South Africa)—also involves in the pact between higher education and society as Schwartzman et al. (2015) call. Altbach and Bassett (2014) stated that BRICS may make sense in terms of economic development but it is an irrelevant grouping to consider the higher education systems of these countries. Even though the academic traditions of these countries are quite different and there is little collaboration, BRICS countries also experience higher demand for higher education all around the world and are also experiencing this increase together with limited financial resources (Tilak, 2013). While the expansion is happening in the private sector, similar to most higher education systems, the public sector is treated with cost-recovery strategies and narrowing down consequently. The expansion has been focusing more on market-driven areas of study such as engineering or management. In the end, Tilak (2013) sees this process in line with the commoditization of higher education. The quality debate in this process is associated with the number of universities in world university rankings—the elite institutions. While the pact has led to economic competitiveness, the success of higher education has heavily been defined by the number of world-class universities from the BRICS countries. There is also a particular emphasis on science and technology that universities in respected countries are aligned with in terms of their research and curriculum (Chang et al., 2018).

We should not also forget these macro level actors—World Bank, OECD, IMF, UN, UNICEF, UNESCO—shaping influential policies on higher education, particularly for developing countries and fund related initiatives in relation to these policies. They generate key statistics and reports on some of the very critical issues of higher education in accordance with the regional developments. These institutions not only present the data on the various aspects of higher education systems but also try to influence the policymaking and strategy formation processes. While these works are valuable for the systems, they are also coming from one source with a particular understanding on the purpose of higher education. The context-bound factors are regarded yet not sufficiently and they end up in an isomorphic perspective.

Finally, it is worth mentioning the world university rankings impacting the strategy formation through their regional rankings and summits. For instance, the Times Higher Education (THE) ranking company is using this method very effectively. THE Latin American Universities Summit, THE Asia Universities Rankings and Summit, Japan University Rankings, Emerging Economies Rankings and Summit, Teaching Excellence Universities Ranking and Summit, Arab University Rankings and Summit (THE Official Website, 2021) can be given as examples. Similar structures can be observed in other world university ranking systems. The imposed upon reality in these ranking systems are measurable performance indicators (through publications, patents, research projects) that HEIs produce rather than a total of added value and impact (through teaching or community service) universities generate within their given society. There are mission statements of universities, which explicitly spell out its role as being ranked in top 100 universities around the world. Yet, this “global competition is [primarily] vectored by research capacity” (Marginson, 2006, p. 1). It is measurable and can be easily linked to innovation (Hazelkorn, 2012), which is the “engine of development in the new world economy” (Castells, 1996, p. 14). They are now “part of the central nervous system of societies ... with an entry point in the higher education quality assessment regimes” (Robertson, 2012, p. 3). The question raised by Hazelkorn (2012)—“Do they encourage a perverse incentive toward the creation of world-class universities at the expense of broader educational goals?” (p. 17)—is a legitimate one to ask in terms of reminding the very essence of HEIs in response to the popularity of these ranking systems affecting the strategy formation. Therefore, the strategy formation of HEIs is heavily steered in numerical and economic terms, connecting to the discussion in the first part of this section.

Essence of the modern university and strategy formation: a *mélange*

The modern university has been going through three transformations since the 1800s (Wittrock, 1993): the resurrection of the university, the rise of the modern-oriented university, and finally, the expansion and fragmentation phase. What we described in this work might call for a new phase of transformation, which stands as an arduous task in front of us. The two perspectives on higher education and operationalization of strategy formation practices cross-regionally indicate that the essence of the modern university has been in the midst of a severe contraction since the 2000s. While it is a truism that governments and international agencies have acknowledged the university’s power of transformative impact on societies, it is ironic that strategies shaped by (inter) governmental organizations and national, international, (bi-) regional, and transnational networks or associations have gained actorness and taken the lead over the actorness of the university itself. In other words, universities have been battling this push and pull between responding and protecting their autonomy as institutions with peculiar self-identities at the same time. We observe two crisscrossing processes—multipolarity and waning criticality—in the five regions’ trajectories that undergird universities’ predicament and find that to the extent that higher education systems with their stakeholders embrace these processes, they inform and shape higher education strategies.

One salient process shaping the development of higher education strategies is multipolarity. This multipolar process involves a wide range of (inter) governmental actors who project their power and influence by means of regional institutions (e.g., CON-AHEC, NAMI, European Union, the Pacific Islands Forum, Asian Development Bank, World Bank, UN, THE ranking company), associations (e.g., AAU, ACURU, ASEAN, UDUAL, UUK), and alliances (e.g., European Universities Initiative). While regionalism through institutionalization seems to lie at the epicenter of the multipolar world of higher education, advancement of economic growth via, say, human capital formation (e.g., Rizvi, 2021), innovation (e.g., Asian Development Bank, 2011), and technology (e.g., Santos and Wilson, 2021) can for the most part be argued to be the driving force behind higher education’s engagement in the multipolar context of the international system. In this new configuration, HEIs’ engagement and strategy formation processes stem mainly from a market-oriented narrative, and regional partnerships serve to formulate and actualize higher education strategies. Yet, the national capacity of a country, even the institutional capacities within the same countries, to embrace this version of

higher education engagement and strategy formation influences the extent to which strategies turn into policies and practices. This is evident in endeavors like free trade agreements (e.g., USMCA, RCEP), common higher education areas (e.g., EHEA, the Latin American Higher Education Area), and the BRICS bloc.

What further complicates this multipolar scene is the geopolitical appeal of such deals. We observe a clear orientation toward enhancing capabilities by allying with relevant actors in a region of interest who can help to weaken the global positioning of other challenger regions, a point also highlighted by Robertson (2010) in the context of European regional higher education governance and by Naidoo (2018) in the higher education “geopolitical rivalry” nexus (p. 607). Scott (2022) also argues that higher education policies, strategies, practices, and purposes have become predominantly affixed to a type of political economy that almost exclusively regards higher education as a “transactional space”—one fraught with “targets, metrics, deliverables and performance with much else missing” (para. 16). The strong association of higher education with this market-based type of political economy narrows, according to him, HEIs’ exercise of their core functions, especially their educative dimensions, to the terms of the market. In this sense, higher education strategy-making as part of geopolitics underpins a new phase of the transformation of the modern university that seems to have attained the feature of a geopolitically strategic global institution as the new oil of geopolitics.

Not surprisingly, there is little discussion of implications for the essence of the modern university in these regional arrangements, which are more prone to marry considerations of geopolitics to considerations to the real experiences of the modern university due to their national circumstances. To illustrate, it is observed that almost all regions have some form of “financial squeeze on HE” as the Asian Development Bank puts (2011, p. 5). The financial constraints are accepted as a natural consequence of the current economic system, but very few question why that is the case. As a result, the higher education landscape shifts from the public good to a private one and it is not being critically evaluated. For example, there is a high student enrollment rate all around the world; the limited financial and human resources are evidential; yet, the shamans expect higher education systems to function magically to accomplish all the goals attributed to them that require investment in human capital. There are no strategies on how to resolve the challenges, such as limited resources or the recruitment of higher education faculty to meet the needs of increasing enrollment. If we keep framing the role of the university in economic terms; then, our narrative is shaped by higher education as merchandise to be produced with the lowest cost but utmost profit. Even if there are available financial resources, it is already determined who will use them on what kinds of research or education by the shamanic actors again. We, therefore, argue that efforts to entangle geopolitics with the essence of the modern university can only offer a putative solution, leading only to mask the challenges confronting systems of higher education.

The multipolar process appears a big shock to the essence of the modern university, ushering in the second process, waning criticality. One interesting observation about this new world of universities is the transitory yet impactful nature of strategies. First off, strategies are overwhelmingly thematic around technology, accountability, transparency, innovation, entrepreneurship, private vs. public good, internationalization, transferability, access, world rankings, partnership/cooperation/collaboration, exchange/mobility, quality assurance, sustainability, and enrollment. Second, they inspire policymaking processes and are modified or renewed accordingly. Examples include the updated template for NAFTA, USMCA; Australia’s Asia engagement vision; the European Education Area; the Alfa PUENTES project; strategic plans in Africa; and the second Cordoba reform in Latin America. What prevails the accompanying strategy documents is the addressing of universities as being conventional into the bargain and the formation of new or modified strategies as a preventing-the-multipolar-system-from-clogging-up-mechanism. The upshot, however, is increased tendencies at the macro-level to glorify the challenges emanating from these processes by new or modified forms of strategies.

A macro-level strategy development process interwoven with economics and geopolitics leaves little room for the critical nature of universities to maneuver for engagement, although the exercise of criticality is how they exercise power and influence. The centralized decision-making in this process privileges the participation of senior higher education leaders, leaving faculty knowledge and expertise and input from students disengaged in the formation of strategies. That said, as the local, national, international, regional, and global institutions, universities bear the brunt of restructuring at the expense of a weakening in their critical essence. New roadmap released at the UNESCO World Higher Education Conference 2022, *Beyond Limits: New ways to reinvent higher education*, recognizes the need for a more inclusive approach and highlights that “students and teachers, ... HEIs, policymakers, international organizations, development partners, the private sector, civil society, youth organizations, social movements, local communities” are all needed if higher education is to contribute to overcome the local and global challenges (UNESCO, 2022, p. 27). The 2030 roadmap outlines six principles—(1) inclusion, equity and pluralism; (2) academic freedom and participation; (3) inquiry, critical thinking, and creativity; (4) integrity and ethics; (5) commitment to sustainability and social responsibility; (6) academic excellence through collaboration rather than excellence—to be followed by all the concerned parties throughout the reinvention process (UNESCO, 2022, p. 23). While these six principles are valuable to rethink the future of higher education strategy formations toward 2030 and beyond, we argue that a step forward to this end should also consider the challenge of macro-level strategy development to the reinventing higher education process. It is also worth noting that country-specific governance regimes impact how HEIs exercise their core functions—research, education, and service. As shown in the 2021 Democracy Index report by the Economist Intelligence Unit [EIU], democratic governance around the world is not on a positive trajectory: Only 6.4% of the world’s population—21 out of 167 countries—lives in a “full democracy” whereas 37.1%—59 out of 167 countries—lives under “authoritarian regimes” (EIU, 2022, p. 6, for a definition of full democracies and authoritarian regimes, see p. 68). That is, many HEIs suffer a decline in democracy, thus face intrusion into their institutional autonomy and academic freedom and significant constraints on their criticality in the search for and production of truth.

What arises from our cross-regional triangulation of higher education strategy formation practices is the reshaping of fundamental functions—research, education, and community service—of the modern university mainly based on a preponderance of

economic urges. We, instead, suggest this new phase in the modern university's transformation be approached as a *mélange*. A *mélange*, according to the [Online Etymology Dictionary \(2021\)](#), is "a mixture ... an uncombined mingling on elements, objects, or individuals." In doing so, we aim to encourage rethinking the modern university's engagement in the strategy-making processes under conditions of multipolarity. Anchored in this analytical approach, we heed [Ashwin's \(2020\)](#), [Birnbaum's \(1999\)](#), [Ozga and Lingard's \(2007\)](#), and [Rizvi's \(2021\)](#) calls to challenge the centrality of the economically oriented perspective in the development of higher education strategies and make the case for the study of the essence of the modern university as a unit of analysis for future research. In line with these scholars, we argue that fixation of strategy formation practices along market lines benefits from a system that condones universities as institutions of human capital formation. In response, we suggest the scholarship of the essence of the modern university renounce feeding this system, be concentrated on educational outcomes, civic role, and socially transformative sides of universities, and couched in educational sciences and higher education studies.

Building this type of scholarship is of dire necessity for the university as an institution to reclaim and promote its fundamental values—institutional autonomy, freedom of inquiry, and indivisibility of teaching and research—and to make sense of diversity in the context of multipolarity. In the absence of sustained countervailing response, a restraining alternative mechanism, the economic orientation toward higher education will continue framing strategies for educational outcomes, civic role, and socially transformative sides of universities, setting the tone for the scope, nature, and scale of a scholarly act for (wider) community engagement. A scholarship of this type requires more than educationally nuanced research efforts but rather proactively promotes engagement within communities of universities, with students, staff, academics, other stakeholders, and societies from a socially responsive standpoint. Formulating our research questions in this manner is apt to disturb the balance of the dominant narrative through acting as a power constraint mechanism. Perhaps this is how we can build proactive ownership around the challenges that confront us as communities of universities. Some questions that might open new windows of opportunity in this regard are as follows:

1. What constitutes knowledge that universities produce?
2. How do academics/university leaders perceive and reason through their roles in the supremacy of market orientation in higher education strategy making?
3. How has the identity of academics evolved out of their experiences within the multipolar world of universities?
4. Who gets to define and govern the identities of academics/students/university leaders?
5. What defines a scholarly act that nurtures the bonds of community engagement in the multipolar world of universities?
6. In what lines do students argue the purposes of university education?
7. How do communities of universities create proactive and collaborative ownership of the purposes of higher education?

Without proactive ownership of academic (scientific) values and interests and collective action, the fact is that the essence of the modern university will go on being denigrated by a global system encumbered with inequalities. The COVID-19 pandemic forced visibility of the existing inequalities within this system when the least developed countries were hit hardest by its dire effects; this situation is by no means over today. It also stressed the delicacy of the system and how narrowly defined its limits are when the economically more developed countries turned inward, focused their efforts on image building and geopolitical positioning. As one remedy, they reframed and/or announced strategic regional trade agreements to shore up their power and global position via higher education. The ongoing global health crisis presents an opportunity for higher education systems to contemplate the true meaning of higher education. Indeed, it is high time that communities of universities said enough.

Whether it was an institutional transformation (Schulze-Cleven, 2016) or a fully-fledged academic revolution (Etzkovits, 2019), scholars agree that the massification of higher education (Tight, 2019), internationalization of universities in Western (Hudson, 2016) and post-Soviet Central and Eastern Europe (Dakowska and Harmsen, 2015), a wide-spread adoption of European Union (EU) initiatives (Vukasovic, 2013), as well as the growing demands of knowledge-based economies on research in the early 21st century (Sørensen et al., 2015) have shaped the current context of knowledge production in Europe. Produced in spaces that bring together the interests and capacities of states, industries, and entrepreneurial universities (Etzkovits and Zhou, 2018; Etzkovits, 2019), knowledge and innovation in Europe are not only key factors of the competitive advantage and economic integration of European nations, but also a pathway to creating a “European knowledge society” (Hoekman et al., 2008).

While purely university-based scientific production is largely a mode of the past, most research and innovation in Europe follows Mode 2 of knowledge generation that is “socially distributed, application-oriented, trans-disciplinary, and subject to multiple accountabilities” (Nowotny et al., 2003, p. 179). The interactions of multiple academic, governmental, and market actors form a triple helix of scientific innovation that is now legitimated by its impact on economic development along with the more traditional expectations of contributing to health, military, and cultural advancements (Etzkovits and Leydersdorff, 2000). Recently, scholars have added a fourth helix to knowledge creation and transfer. Civil society is seen as a key participant in the

diffusion of knowledge and a source of a bottom-up approach to democratic and accountable scientific practices (Carayannis and Campbell, 2012).

In this article we examine the current roles of European states, markets, and universities in knowledge production and review the critiques of academic entrepreneurialism and neoliberal market influences on European higher education.

States and supranational organizations

As the political power of the state in Europe gradually moved to supranational structures like the EU (Lavdas et al., 2006), institutions of higher learning were strategizing to respond to higher enrollments, growing student mobility across national borders, and increasing global competition from knowledge-led economies in North America and Asia (Sursock and Smidt, 2010). The European universities' answer to these pressures was to europeanize (i.e., adopt EU policies and initiatives directed at national higher education sectors) (Vukasovic, 2013) and to harmonize (i.e., align their national research systems with labor market regulations, property right laws, and academic degree nomenclatures) (Hoekman et al., 2008). Arguably, the two main European policies driving that response are the Bologna Process and the Lisbon Strategy (Keeling, 2006; Sursock and Smidt, 2010).

Bologna process

If the Lisbon Strategy is more of the call to arms, the Bologna Process is how to take said action. The European Bologna Process is a set of strategies to align national study programs and regulations across European countries in order to develop European Higher Education Area (EHEA) (Huisman and van Vught, 2009), a competitive European market, ease of transfer across institutions, and to attract international students (Naidoo, 2011). This strategic alliance seeks to increase Europe's overall higher education market share and attract the best intellectual minds to the area (Robertson, 2010). While the Bologna Process does not operate under the auspices of the European Union, it was the original 29 ministers who came together in Bologna, Italy in June 1999 and created the European Higher Education Area by 2010. The goal was to increase the mobility, employability of Europe's higher education system and the international resurgence of the Continent (Gaston, 2010) through the assurance of more compatible and coherent higher education systems.

The original Bologna Process sought to accomplish six broad action items: (1) the creation of easily readable and comparable degrees documented through diploma supplements provided to every student; (2) the organization of higher education (undergraduate, masters, doctoral; also known as the three cycles of higher education qualifications); (3) the management of education credentials through a recognized system of credits; (4) the encouragement of educational mobility through a recognized system of credits; (5) the encouragement of educational mobility through the expansion of cross-border opportunities for studying and teaching; (6) the development of a stronger commitment and promotion of dimensions of curricular development, interinstitutional cooperation, mobility schemes and integrated programs of student, training and research. (Bologna, 1999; Gaston, 2010, pp. 35–36). The Ministerial Conferences, have held every 2–3 years, assess the progress made within the EHEA and to decide on the new steps to be taken. In 2020, 48 European (and other) countries were involved in this process (EHEA, 2020) where the process addressed research at the supranational level (van Vught, 2009).

Since 1999, the Bologna Process acquired political and economic dimensions along the way (Tomusk, 2004). Politically, it allowed the European Commission to exert more influence over national higher education systems and added legitimacy to the ambitions of former communist states that wished to join the European space (Tomusk, 2004). Economically, it charged European universities with contributing to the creation of European knowledge society. The framing of the Bologna process in the discourse of the knowledge economy and society enforced the nation states' obligation to the process and enabled them to commence higher education reforms (Ravinet, 2008).

Lisbon strategy

The Bologna Process and Lisbon Strategy are often discussed together. In relation to knowledge production, Lisbon is related directly to national economic competitiveness, rather than the whole of workforce development and, as such, we discuss it here.

The Lisbon Recognition Convention is an agreement on the recognition of educational qualifications in Europe that were adopted at the COE/UNESCO meeting in April 1997. It encourages consistent, convenient assessment of educational credentials earned in any European country. The Lisbon Recognition Convention and Bologna Process share a priority of higher education and are often confused (Gaston, 2010). The Bologna Process is a part of the overarching Lisbon Strategy. Envisioned at the meeting of the EU heads of states in Lisbon in 2000, the intention of the Lisbon Strategy is to enable Europe to increase its prosperity and, in turn, to enhance its social models (Rich, 2010). To achieve this, the European Council called for the EU to become the most competitive and knowledge-based economy in the world, capable of sustainable economic growth with more and better jobs and greater social cohesion. This ambitious vision aimed to transform not only the European economy but also the social welfare and education systems in European nations: "Key elements of the strategy include budgetary sustainability, better regulation, improved tax and benefit systems, and improvements in education and training systems, and investment in research to maintain comparative advantage over other parts of the world" (Rich, 2010, p. 566).

Thus, the Lisbon Strategy explicitly linked research to economic development and set a goal of transforming the European Union into the most globally competitive region (Keeling, 2006). The implementation of the Strategy faced some setbacks, and the re-launch of the initiative in 2005 was criticized for its departure from the social goals of societal cohesion and inclusion in favor of an economically driven pursuit of job creation (Dieckhoff and Gallier, 2007). Nevertheless, one element of the Strategy that

proved most popular among the universities—funding of research—earned the initiative considerable legitimacy among academics and university administrators (Keeling, 2006).

The diverse legal frameworks, market regulations, and higher education systems of European nations presented a further challenge to European knowledge production and transfer. Removing barriers to scientific collaboration within the EU through “harmonization of national research systems” included the alignment of property rights laws, labor market practices and regulations, and diploma systems (Hoekman et al., 2008, p. 736). The harmonization efforts, as critics points out, made it possible to discuss a European higher education system rather than systems, yet the new configuration is marred by geographic disparities (Tomusk, 2004). Elite and capital regions with best resources and top scholars collaborate within themselves, excluding the periphery (Hoekman et al., 2008). In Central and Eastern Europe knowledge production remains linked to legacies of command-driven economies and to transitions: as these nations transitioned to capitalist market economies, and societies to post-communist welfare states, their higher education and research systems inherited the issues of access, funding, and governance of their predecessors (Kwiek, 2012).

Industry

In addition to securing funding for their research activities, universities are motivated to collaborate with industry to improve the quality of their scientists and see their innovations applied to real-life world (Muscio, 2010). In the 1980s and 1990s, the experience of high-technology-based economic growth around Cambridge in the UK, Twente in the Netherlands, and in Finland became exemplars of successful university-industry collaboration and gave impetus to a range of government supported initiatives such as science parks and technology transfer offices (Kitagawa, 2005). These initiatives were conceived as important elements of the European nations’ innovation systems that consist of “competitive firms and a competitive environment, an effective educational system, strong university research, a legal system with property rights, and a capital market that includes venture capital” (Link and Scott, 2007, p. 669).

Science parks

Depending on the accepted terminology in a specific European regional and national context, science parks are also known as hi-tech parks, innovation centers, technopoles, and campuses (Ng et al., 2019). Defined as “a real estate or an area development, managed by an on-site management company [and] home to knowledge organizations, such as research institutes, HEI, and firms in all business development phases” (Ng et al., 2019, p. 726), science parks successfully broke apart the monopoly of universities on the production of knowledge in Europe (Etztowitz, 2003). Over half of all European science parks (55%) are publicly owned by local and regional governments and higher education institutions, 14% are privately owned by private universities and businesses, and the remaining third (30%) have a mixed private-public control (Kriemadis, 2018).

The explicit assumption underlying the foundation of science parks is that they contribute to national competitiveness through a two-way flow of innovation between universities and industry (Link and Scott, 2007). On the basis of the purposes and characteristics of resident organizations, European science parks can be classified into three groups: incubators, research locations, and cooperative locations (Ng et al., 2019). The goal of science parks is to produce value through their knowledge and business ecosystems, and universities and research institutes play key roles in that task at research and cooperative locations (Ng et al., 2019). When located in cities, science parks form knowledge community precincts, contributing to innovative urban development and renewal (Olçay and Bulu, 2016) and become vital part of urban knowledge economies (Teixeira et al., 2019).

Talent recruitment and management is an important function of science parks that complete for best graduates and maintain networks with the alumni of tenant higher education institutions (Löfsten et al., 2020). As stakeholders in the success of science parks, governments can invest in the promotion and internationalization of their parks’ brand for greater contribution to their nations’ knowledge economies (Cadorin et al., 2019). Skilled migrants in Europe also make a positive impact on the growth of published academic articles and patented innovations in industry (Bosetti et al., 2015).

Technology transfer offices

Along with a more traditional commercialization of intellectual property through individual patents and licensing (Thursby and Thursby, 2007), technology transfer offices offer universities an opportunity to commercialize innovation by focusing on selected high-quality inventions for reputation building (Siegel et al., 2007). In transition economies of Central and Eastern Europe commercialization of university research occurs directly as a result of the direct industrial funding rather than through government-created technology transfer offices (TTOs) (Belitski et al., 2019).

Based on the assessment of potential profitability of the inventions, TTOs as owners of universities’ intellectual property typically choose one of the two strategies: licensing the inventions to existing companies or creating spin-offs, “new companies founded to exploit a piece of intellectual property created in an academic institution” (Shane quoted in Algieri et al., 2013, p. 383). In addition to the inventions’ potential, the decision about licensing or spin-off depends on the business expertise of the TTO staff and the university’s intent at the local level as well as the country’s intellectual property rights legal framework and the government funding system at the national level (Bengtsson, 2017). In all cases, however, the TTO’s hold a substantial advantage over individual academics because they have access to networks among firms and in industry to make commercialization successful (Siegel and Wright, 2015).

Knowledge and technology transfer offices typically cover three areas of activity: they support the intellectual property of academic researchers by protecting their research results and negotiating licensing contracts; they offer research support by overseeing researchers’

collaborations and contracts; and they assist with the business planning and funding of spin-offs (Brescia et al., 2016). Thus, to operate successfully TTOs must claim expertise both in science and in business. This dual identity may lead to legitimacy problems with academics and managers alike and require organizational efforts to meet normative expectations of both parties (O’Kane et al., 2015). At the same time, academic departments’ reputation for producing high-quality research and universities’ research ranking positively affect the use of TTOs: on the one hand, high-output departments make a more frequent use of TTOs than their less productive counterparts, on the other, companies are likely to contact those TTOs that are located at well-ranked universities (Muscio, 2010).

There are reported gender differences in knowledge and technology transfer in Europe. For example, research groups led by men are better positioned in the collaborative networks with industry and they are more likely to express interest in collaboration with external companies (Calvo et al., 2019). Furthermore, there is evidence that male scientists, more so than their female colleagues, are deterred by the difficulty of coming back to the academic position if their spin-off enterprise fails, while female scientists are more constrained by a lack of human resources and exchange with peers than their male counterparts (Sinell et al., 2018).

Entrepreneurial universities

Since taking hold in the mostly European and North American academic literature in the 1980s, the concepts of entrepreneurial university and academic entrepreneurialism have developed side by side to describe, predict, and critique the universities’ involvement in commercialization of research and creation of spin-off business-oriented ventures (Mascarenhas et al., 2017). In addition to its clear business connotations, entrepreneurial university is also described as “adaptive,” “proactive,” and “innovative” (Clark as cited in Schattock, 2005, p. 17), financially self-reliant and independent of the state (Schattock, 2005). The entrepreneurial university is also risk-taking, both intellectually and economically (Barnett, 2005). Because entrepreneurial universities are more responsive to the market, entrepreneurialism leads to diversification of institutional forms and missions and subjects universities to more global pressures (Schattock, 2005).

Unlike the US entrepreneurial university model that is based on the research mission, entrepreneurship of the European universities traditionally centered around their teaching mission (Etzkowitz, 2003). At the same time, eager to build up their knowledge-based economies, many European governments now task their higher education institutions with a third mission of service in the name of national and regional economic development (Williams and Kitaev, 2005). This third mission has acquired a particular strategic importance since the launch of the Lisbon Strategy. Entrepreneurial universities not only bring in technology and innovation to their locales but also serve as “reputational shopping malls for regional markets” that compete globally against each other and against the United States (Rinne and Koivula, 2005, p. 106).

Academic entrepreneurialism in Europe takes different forms in open and controlled markets, depending on the roles of national governments in the regulation of higher education systems. Barnett (2005) differentiates between soft and hard entrepreneurialism. Institutions’ explicit pursuit of profit through tuition price setting, revenue-generating services, program offerings, etc. characterizes a hard approach, which can take the form of unbridled entrepreneurialism in open markets and is curtailed in controlled markets. By contrast, soft entrepreneurialism is diffused in the culture and operations of universities and university departments. The soft approach, encompassing civic entrepreneurialism in open markets and hesitant entrepreneurialism in controlled markets, is grounded in the conceptualization of higher education as a public good and aims at anticipating and meeting the needs of the society through innovation in research and instruction (Barnett, 2005).

There are some notable disciplinary differences in the European professoriate’s perceptions of entrepreneurialism and knowledge transfer. More academics in natural sciences think of their departments as highly entrepreneurial than do their colleagues in social sciences (Kalar and Antonicic, 2015). Furthermore, those who view their departments as highly entrepreneurial tend to view knowledge transfer as beneficial rather than harmful to the academe and are themselves more likely to engage in entrepreneurial activities (Kalar and Antonicic, 2015).

Nevertheless, many see entrepreneurialism as a double-edged sword: on the one hand, it is beneficial as it leads to creativity and academic innovation and greater institutional autonomy; on the other, it is constraining because it leads to commercialization of research and instruction and less academic freedom for faculty to pursue their research, especially if their agendas have little market value. This tension is well captured by Rinne and Koivula, who observed that “the entrepreneurial university has been seen as a natural continuation of the development of the university ... but also as a deformed child of the research university” (Rinne and Koivula, 2005, p. 104).

Critiques of knowledge production in Europe

Scholars critical of European and North American knowledge production point at its embeddedness in the neoliberal market ideology and question its Euro-centrism. They observe that knowledge production is linked with knowledge legitimation and the “socially destructive effects of marginalizing forms of knowledge production” and contend that the designation of “developed” and “developing” assumes inevitability and appropriateness of converging on the Western market models of modern development (McGovern, 2012, p. 5). Other critics, approaching knowledge production from a Foucaultian poststructuralist perspective, view higher education policies and reforms as a form of governmentality, a political rationality aimed at directing the development of institutions and individuals (e.g., Ozga, 2008; Laalo et al., 2019; Day and Pirrie, 2021). Feminist, postcolonial, and Critical Race Theory scholars of higher education take a stand against a systematic disadvantage of women and people of color in the

production of knowledge that is dominated by white male academics and Western academic traditions (e.g., Blackmore, 2021; Joseph-Salisbury, 2019; Pasque and Carducci, 2015). In the following discussion we will present these lines of critique in some detail: Academic capitalism, including accountability and privatization; governmentality; and epistemic injustice.

Academic capitalism

Universities are often important cultural centers, spaces of the most cutting-edge research and development, and places of independent and critical thought (Altbach, 2016). University libraries contribute significantly to the knowledge economy as major repositories of knowledge and a greater amount of information is available open access through the internet, google scholar, Wikipedia, MOOCs, and global universities coordinated from a local institution. Yet, a global, knowledge-based economy is fundamentally different than other tenets of economics because knowledge behaves differently than other commodities and is particularly more difficult to measure (Neff, 1999). Knowledge is often driven by the economy and imperialism (Naidoo, 2011), pursuit of profit (Chomsky, 1999; Giroux, 2002; Giroux and Giroux, 2004), grants (Posselt, 2009), patents, copyrights commodifying the core academic function (Slaughter and Rhoades, 2004), corporate sponsorship (Bush, 2009) and General Agreement on Trade in Services (GATS), of which Australian and UK universities have led the way (Rhoades and Liu, 2009). The global economy is the most powerful force impacting universities today (Rhoades and Liu, 2009). This is what Apple (2006a) calls the era of conservative modernization or “a new hegemonic bloc ... a very creative articulation of themes that resonate deeply with the experiences, fears, hopes, and dreams of people as they go about their daily lives ... integrated ... with racist nativist discourses, within the economic dominant forms of understanding, and within a problematic sense of tradition” (pp. 27–28). This European-American socio-political context connects neoliberalism, neoconservatism, authoritarian populist religious conservatism, and managerialism (Apple, 2000, 2006a,b). This era of conservative modernization seeks to undermine certain conceptualizations of freedom and democracy and supplant them with conceptualizations that serve the private interests of the ruling class (Gildersleeve et al., 2010).

Accountability systems have become entrenched focusing on performance funding (in which state allocations are linked by formula to performance on an indicator or set of indicators), performance budgeting (in which performance data are used in budgeting but without a formula), performance reporting (in which there is no explicit link between the data reported and the budget process), or a combination (Zumeta and Kinne, 2011, p. 178). European institutions have justified this accountability and institutional autonomy logic through competitive logic. This logic breeds performance management, accreditation and rankings (Erkkilä and Piironen, 2014). International rankings such as the Times Higher Education ranking, the Shanghai ranking and Newsweek (a mix of Times and Shanghai) differ considerably and there is a concern that continental Europe is falling behind (Winckler, 2008).

Private, individual good Institutions of higher education have transformed from a focus on the public, social good to that of the private, individual good (McMahon, 2009; Pasque, 2010/2014). In Europe as well as in many countries, a shift of financial burden is being made from the financing of the taxpayer to the student (via tuition and fees) and from the public to the private sector (Newby, 2008). Private education is one of the fastest growing and dynamic areas of higher and postsecondary education throughout Europe and across the globe as 30% of global higher education enrollment is private (Altbach, 2016). Corporate sponsorship has benefited both the public and private institution, with conditions favoring the corporation including increasing the size of the potential labor pool, securing qualified employees for their own use, and negotiating special tuition rates (Bush, 2009). Ownership, copyright and profits matter as the commodification of higher education has taken hold in recent years. Benefits to the university may include increased revenue, lower cost, increased communication with corporate stakeholders, and increased access to potential employers. Corporate sponsorship colonization is defined as benefiting the advantaged institution and exploiting the less advantaged institution (Bush, 2009; also see Dunning, 2000). This has been termed alliance capitalism, where alliances are built between institutions and different stakeholders such as a private firm, public institution, regional and national government, interest groups, businesses, and beyond (Dunning, 2000).

Entrepreneurialism and Europeanization as governmentality

Poststructuralist critics of entrepreneurial universities and Europeanisation processes employ Foucault’s concept of governmentality to uncover political rationalities that govern European higher education policy making and the techniques of self that frame the behaviors of students, academics, and managers as “economically self-interested subjects” (Laalo et al., 2019, p. 96). From this perspective, the Bologna Process not only streamlines national systems of higher education for easier student mobility but also directs higher education institutions, academic communities, and student populations to become globally competitive entrepreneurial actors for their own private benefit and the benefit of the EU market (Nokkala, 2015). To put it differently, the creation of European knowledge society and the Europeanization measures aim at generating knowledge not only for industrial innovation but also—particularly in human sciences—for managing education and welfare of populations and as such are enmeshed in political technologies of European states and supranational organizations (Ozga, 2008). Framed by the ethics of neoliberalism, the EU discourses that promote entrepreneurship in higher education “to make stronger Europe” create a normative ideal of what a competitive university and an innovative academic look like (Laalo et al., 2019, p. 95). Emphasizing the market reasoning, that ideal explicitly neglects non-economic purposes of universities, such as the development of critical thinking and contestation of democratic ideas (Laalo et al., 2019). The role of university instructors is then transformed into managers of their own intellectual outputs and student satisfaction (Day and Pirrie, 2021).

Epistemic injustice

Epistemic injustice is a regulatory form of knowledge production that starts with the concept that social power is the capacity humans have to act and influence the social world, in this case, in the context of a European university (Fricker, 2008 also see www.oxfordscholarship.com). Power exists when put into action (Foucault, 1982) and *epistemic injustice* occurs when a wrong done to a person specifically in their capacity as a knower by a hearer (Fricker, 2008). This epistemic side of colonialism is the “devastating effect of the ‘disappearing’ of knowledge, where local or provincial knowledge is dismissed due to privileging of alternative, often Western, epistemic practices” (Dotson, 2012a, p. 236). There are three types of epistemic injustice: testimonial, hermeneutical, and contributory.

Testimonial injustice, a form of epistemic injustice, occurs when prejudice causes a hearer to give a reduced degree of credibility to a speaker’s words based on the speaker’s perceived gender, race, sexual orientation, class and/or other identity. An example of testimonial injustice is when a campus police officer does not believe you because you are a Black faculty; or a faculty wrongfully deflates your perspective as a student because you are a woman in the sciences. The speaker in these cases is wronged. *Hermeneutical injustice* occurs when there is a gap in collective or social-interpretive resources based on identity, and one is structurally prejudiced. Fricker offers an example of a new mother in the 1960s who, after participating in a small group feminist discussion, comes to understand that her depression was not her fault nor what her husband blamed her for previously. In this case, hermeneutical injustice is based on a structural definition of new mothers during that time period, and one could have this definition inflicted on her (by her husband) or she could inflict it on herself (also known as *internal oppression*, Lorde, 1984/2007). Hermeneutical oppression puts someone at a prejudicial disadvantage when it comes to making sense of their social experiences and systemic understanding, in this case of a new mother, and this sense-making changed over time to be defined as postpartum depression. Hermeneutical injustice at a European university exists when one suffers sexual harassment in a campus work culture that still lacks understanding of that critical concept. In this case when hermeneutical injustice is present, it is not the speaker’s lack of intelligibility but it is due to the deprived interpretive resources available to the speaker (Fricker, 2008). Dotson (2012a) extends understandings of epistemic injustice to include *contributory injustice*, which arises from a willful denial of epistemologies by the hearer. It occurs when diverse voices and experiences often counter to the dominant paradigms are offered but immediately or preemptively rejected. In this case, the hearer is unwilling to acknowledge the diverse ways of knowing (Dotson, 2012b), such as a campus climate that structurally supports harassment even after the #metoo movement (Founder T. Burke) and campus awareness.

With its focus on the economic outputs, the neoliberal entrepreneurial university inflicts epistemic injustice on women faculty and administrators by systematically disregarding the structural and cultural barriers to their advancement (Blackmore, 2021). Knowledge production in the EU remains dominated by men, with room for growth among women and transgender people. Elsevier’s (2020) report “The Researcher Journal through a Gender Lens” examines knowledge production between men and women regarding research, career trajectories and perceptions across the EU (referred to as the EU28) as well as 15 countries in 26 fields and disciplines. The report lays out disparities with women having a smaller footprint in the research landscape, grants and patent applications than men. In research authorship, women publish for nearly as long as men over the course of their career however the ratio of women to men as authors has decreased over time. The gender balance in the EU is slowly improving, with approximately 1/3 of all researchers identifying as a woman (p. 49). For more on transgender equality see the European Commission (2020).

Institutionalized in university curricula, organizational structures and cultures as well as scientific ethos, Eurocentrism and whiteness continues to dominate spaces of learning and knowledge production in Europe (Joseph-Salisbury, 2019). Engrained in the fabric of academic disciplines, Eurocentrism perpetrates what Alcoff (2017) calls a transcendental delusion, “a belief that thought can be separated from its specific, embodied, and geo-historical source,” claims universality and de-legitimizes other epistemologies that come from non-Western geo-historical sources (p. 397). Thus, Eurocentrism is predicated on epistemic injustice. Globally, epistemic injustice is manifested in the creation of “scientific ghettos” in the Global South where knowledge production is often directed by the interests and publication venues of the Global North, of which the European Union is a prominent actor (Dübgen, 2020).

Concluding remarks

The European Union and colleges and universities throughout the EU face a double pandemic of Covid-19 and racism. Covid-19 has caused EU higher education institutions to focus on physical health of their students, administrators and staff; environmental health factors such as cleaning, classroom chair locations, limiting visits to campus, and beyond; request faculty switch to distance learning, to name a few. “The other pandemic: Systematic racism and its consequences” (Elizondo-Urrestarazu, 2020, p. 1) has been a global initiative of awareness, protest, and a re-construction of knowledge around race where education serves as one of the main foci (along with housing, banking, criminal justice, public and health) of internalized, institutional and systemic oppression.

Myriad organizations such as Equinet, the European Network of Equality Bodies, have focused on the Covid-19 response and systemic racism. The European Network Against Racism (ENAR) has worked toward educating people about racism, including securing equality data, racial profiling, and policing. Further, the EU Fundamental Rights Agency (FRA) (2019) published a report focusing on discrimination faced by Black people in the EU which, we argue, continues to limit knowledge production throughout the Continent.

As institutions, states, supranational organizations including the EHEA, partnerships and cross-collaborations change in this new era, the production of knowledge will continue to change. Covid-19 and racial injustice have had an impact on the Bologna Process, science parks, technology transfer, and the like. In the field of higher education specifically, time is ripe to contest the post-colonial heritage of European higher education as a “powerful system of knowledge, constructed in contrast to, and in conflict with, non-European ‘intellectual traditions’” and to examine its neoliberal global ambitions (Ploner and Dana, 2020, p. 375). Challenging the racialized knowledge production in the historically white universities of Europe and the testimonial injustice that non-Western academics face in establishing their scholarly credibility in Europe (Thapar-Björkert and Farahani, 2019) should contribute to more equitable, inclusive, and productive research partnerships and collaborations.

Introduction

Today, most universities—especially those claiming to be “world-class”—tend to profess missions focused on leading in the solution of common global challenges, such as the United Nations Sustainable Development Goals and Industry 4.0 (Stensaker et al., 2019). Many such institutions serve as “flagship” universities, taking responsibility for the development of the nation-states wherein they are based (Douglass, 2016). Under the new geopolitics of higher education, these world-class universities play an increasing role in promoting the global public good (Marginson, 2018). Two ideas underlie this exploration: first, that universities (or at least world-class universities) share a common identity as academic institutions, globally; and, second, that they serve beyond their national borders.

Yet universities throughout the world have frequently faced crises, as interventions from both religious and secular powers have challenged their academic freedom and autonomy. This situation continues even today (Neave, 2001). In regions with non-European traditional civilizations, such as East Asia, modern university systems were launched, developed, and transformed in particularly close association with nation-building after the mid-19th century. The articulation of Western imported ideas around universities—alongside Eastern intellectual traditions and identities—has constantly been a central issue throughout this process (Chan et al., 2017).

Recent decades have seen the dramatic rise of East Asian national economies, based on science and technology. This has driven national leaders and higher education researchers in the region to seek identities for their own universities and higher education systems that are different from those of Western universities—and that are both similar and diverse within the region (Marginson et al., 2011). The emergence of globally top-ranked universities in East Asia has accelerated this trend (Yonezawa, 2021). For example, the achievements of Singapore’s highly ranked top universities indicate that it is possible to establish world-class universities on a strong national basis. Yet a clear consensus on academic freedom and university autonomy is still lacking, while substantial changes to implement more decentralized university governance are ongoing.

The translation activities at a university can be defined as (1) the translation of the texts it provides and uses, (2) the translation for the lectures and academic dialog, and (3) the development of the university system and the concept of the university through translation. The modern need for a more complex global “translation” of the identity and concept of a university constitutes a departure from the medieval European universities, where the main functions played by translation were limited to (1) the translation of text from Arabic and other languages, into Latin as the common language; and (2) lectures and dialogs, among academics from various linguistic backgrounds, carried out in Latin. While medieval European universities had varied backgrounds and characteristics—such as the universities born in Bologna and Paris—there was a basic consensus on the system and concept of universities as autonomous academic communities, authorized by secular and/or sacred powers (Neave, 2001).

The translation and definition of the contemporary university in East Asia, in contrast, comprises all three perspectives noted above. East Asian universities’ concepts and identities have been established and transformed amid diverse translations—both to and from the multiple languages and cultures existing in the region. The concept of the university in East Asia has thus been formed and transformed in close association with the various societies of the region, through the path dependence mechanism where concepts introduced through translation in the past could be alive and transformed internally.

This article aims to examine how concepts around the “university” were formed and developed in East Asia—with a particular focus on translation as a function for the transmission, consolidation, and sharing of knowledge. From the late 19th century onwards, the region’s universities were formed—following, as models, the universities developed by the modern nation-states of the Western world. Under the strong influence of nationalism, East Asian universities were created using each country’s own national language. This article analyses how the formation and development of the “university” as a concept have been influenced by changing international and national social contexts—first, from the construction of modern university systems to the end of the Cold War; and then continuing on into the globalization age, up to today.

Implantation and development of the modern university, through translation (from the mid-19th century to the 1980s)

Japan: society based on translation

The use of the term “*Daigaku* (大学)”—or “university”—in Japan’s educational history is basically limited to its history as a modern nation-state; a Western-style government was established through the Meiji Restoration in 1868. Amano (2009), however, argues that Japan’s original university initiative, at the beginning of the Meiji Restoration, had the characteristics of a “restoration,” one that aimed to revive the “*Daigaku-Ryo*”—a higher education and research institute existed in eighth century, which strove to introduce advanced civilization from China—as a symbol of Japan’s own inherited intellectual history. Under the intervention of the new modern government, the building of modern universities and schools proceeded through various rather conflicting initiatives and interaction among different intellectual groups. These included: (1) *Yogaku* (Western study), which had been developed through the limited contact with and importation of Western civilization during the Edo period; (2) *Kangaku* (Chinese study), based on the continuous intellectual input received from China since ancient times; and (3) *Kokugaku* (Japanese study), representing Japan’s own intellectual heritage (Yonezawa et al., 2017). The concept of the modern Japanese “university” had thus been created and verbalized in the Japanese system, prior to modernization. As an East Asian tradition, this included the training of bureaucrats and technocrats—which was strongly expected and emphasized as a function of universities and higher education institutions.

Still, Yoshimi (2011) sees the concept of *Daigaku* as one based on the Humboldt philosophy of research and education, developed in Germany since the beginning of the 19th century—a major university model that influenced Japan. The philosophy and reality of the university were diverse, especially among private institutions. Joseph Hardy Neesima and Umeko Tsuda, who were originally born in Japan and studied at liberal arts colleges in the United States, started their own schools—which they first opened as English language schools—in Japan after the Meiji Restoration. Many private higher education institutions started out as professional training schools in various fields (e.g., law, medicine, and languages) and were later transformed into comprehensive universities (e.g., Doshisha University and Tsuda University).

The new government, established in 1868, founded and developed its Western-style education system through a series of ordinances that were mainly developed through trial-and-error. The Education System Ordinance of 1872 planned to establish eight *Daigakko* (大学校; *Grandes Écoles*) in Japan; yet these new higher education institutions were not clearly defined and the timeline for their establishment was not stated. The Education Ordinance of 1879, which replaced the Education System Ordinance, contained a *pro forma* legal definition of the *Daigakko* as an institution where specialized courses in law, science, medicine, literature, etc., were to be taught.

In 1877, the Tokyo *Daigaku* (東京大学; the University of Tokyo), was established as the first national university in Japan. It was a Western-style comprehensive university offering faculties of law, science, letters, and medicine. The term *Daigaku* became an official word for “university,” thereafter. Merging Imperial College of Engineering as the faculty of engineering, the University of Tokyo was renamed “Imperial University” in 1886. Its name was changed again—this time, to “Imperial University of Tokyo”—when Kyoto Imperial University was launched as the country’s second imperial university in 1897. According to the Imperial University Ordinance, enacted in 1886, these imperial universities aimed to offer instruction in the arts and sciences, which were indispensable requirements for the nation, and to conduct in-depth research. The 1918 University Ordinance officially authorized private universities, reiterating the aim of such universities (as in that of the imperial universities, above) and specifying that universities should pay attention to the cultivation of personality and national thought. This was also applied to Keijo Imperial University (in what is now Seoul, Korea) and Taipei Imperial University (in what is now Taipei, Taiwan), under Japanese colonization.

After World War II, Japan’s educational system was comprehensively reformed. Under the Allied occupation and with the arrival of the US Education Mission, a new university system was developed in Japan—with the accompanying “translation” between English and Japanese languages and traditions (Tsuchimochi, 1993). The 1947 School Education Act states: “the university aims to educate and research a wide range of specialized arts and professional knowledge, and to develop intellectual, moral and applied abilities, as well as to widely impart knowledge as a center of (the) academy” (Article 52). There are clearly significant changes to the rules governing the relationship between universities and the state, before and after the war.

After World War II and up to the end of the Cold War, the discussion around higher education research and policy focused on differentiating functions to provide mass and universal higher or tertiary education. Japan was ahead of its neighboring countries in East Asia at that time, in terms of broadening participation in higher education—with private universities and higher education institutions playing a major role in the expansion of the country’s higher education system. Until the end of the Cold War, Japan thus made almost no serious reference to models from neighboring East Asia countries to indicate the direction for Japanese universities and higher education.

In the 1970s, the discussion around higher education in Japan was oriented toward reaching the masses. Professional training colleges were launched in Japan in 1976, as non-university post-secondary education institutions—using the trend toward promoting the non-university education sector in Europe and the United States as a reference. Junior colleges, in contrast, have been constantly recognized as part of the university sector in Japan, while their de facto mission became short term higher education for female students. More recently, in 2019, the Japanese educational sector launched a new category of “professional university,” to meet needs for professional and vocation-oriented university education. Along with these, various *Daigakko* serve educational needs linked to ministries and agencies other than the Ministry of Education, Culture, Sports, Science and Technology (MEXT), and are affiliated with said institutions (e.g., the National Defense Academy falls under the Ministry of Defense).

(Greater) China: seeking a hybrid identity

In contrast with Japan, the conceptualization and formation of modern universities in China reflect various aspects of China’s unique context. First, in the Qing Dynasty of the 17th to the beginning of 20th century, the Manchu were the dominant ethnic group. Although the group’s native language was Manchu, administrative Chinese (the official language of Beijing) was widely used as a common language. Academic institutions’ activities were conducted in Chinese, as were the Chinese imperial examinations. Literature, knowledge, and other aspects of culture were also widely distributed to neighboring countries in Chinese.

Second, some elements of Western literature and knowledge had already been translated and transplanted into Chinese. Literature on Western societies that had been edited in Chinese—such as the 1842 “*Haiguo Tuzhi* (Atlas and Description of the Countries beyond the Seas)” —made a great impact in Japan at the end of the Edo era (Agawa, 2011). These translations were different from those translated into Japanese, which had the character of “transplanting advanced civilization to the local society.” The Chinese-language translations, instead, were based on Chinese thought. Their stance was open to the concept of “the application of Western learning.” Here, Western science and technology were intended to be coupled with Confucian thought—as well as with the Chinese imperial examination system and civil servant training, which had an impact on meritocracy through examinations in Western society. For example, the *Beijing Guozijian* (北京国子监), the Dynasty’s higher education institution—which functioned in close relationship with the national civil servant examinations and training—was reorganized into the Imperial University of Peking in 1898. It then became Peking University in 1912, after the Xinhai Revolution. A reform to strengthen the features of the modernized university was promoted, after Cai Yuanpei became President in 1917 (Yang, 2003). Along with the impact of Western universities, China’s establishment of the Imperial University of Peking was also influenced by Japan’s establishment of modern universities (Zhao, 1999). In other words, the *Daigaku* 大学 was first formulated as a modern concept of “university” in Japan. The *Dà Xué* 大学 in China referred to this and was defined as a comprehensive university. More than three such institutes were established under the regime of the Republic of China before World War II (Liu and Xu, 2004). Japanese intellectuals like Okuma (1922)—the founder of Waseda University, a top private university in Japan—intended to maintain a harmony between the East and the West as two equal civilizations. This is consistent with the positive acceptance of international students from Asia, especially from China, by Japanese universities and higher education institutions (Li and Liu, 2015).

Third, since China is a nation-state that covers a vast expanse of land and diverse regions—including, especially in its border regions, a variety of multi-ethnic communities—it experiences institutional transplant due to direct and indirect interference, as well as influence from foreign countries (non-Chinese language-speaking areas). This has also had an impact on the establishment of modern universities in China. Examples include a group of universities in Hong Kong that were established after the Opium War—as well as Kenkoku University, founded in Manchuria. The Tsinghua Xuetang, as the predecessor of Tsinghua University in contemporary China, was also established as a preparatory school for study at American universities. The establishment is a result of diplomatic negotiations with the United States (Hayhoe, 1996; Saito, 1990; Zhu, 2013). Private universities in China were likewise established with support by the US, Europe and Japan. This spurred a diversification of Chinese universities, up to the first half of the 20th century.

Fourth, Greater China—as an area with a common Chinese language and civilization—has been spreading across multiple countries and administrations. Accordingly, it encompasses various interpretations of the concept of “university.” From the Xinhai Revolution in 1911 to the founding of the People’s Republic of China in 1949, universities in China experienced rapid changes due to different localities’ separation and merger at the hands of warlords, civil war, and the Sino-Japanese war.

In the communist party-controlled areas of the People’s Republic of China, universities responsible for fostering leaders and secretariats in the liberated areas became the mainstream universities, together with universities supported by churches and private universities. There was a reorganization of domestic universities and higher education institutions.

In 1949, the Chinese “People’s Political Consultative Conference Common Program” was announced. Based on the experience of the areas liberated by the communist party, the new democracy education would absorb a significant experience of the education under the communist regime, taking advantage of the Soviet experience. A large number of supervisors from the Soviet Union were then dispatched to universities in China. The number of comprehensive universities that aimed at fostering experts decreased, while the number of specialized colleges increased. The government’s educational department was also centralized and institutions were adjusted to put a stronger emphasis on science and engineering (Otsuka, 1996; Yang, 2003).

The development of China’s universities in 1950s and 1960s became more dependent on the changes in its domestic and international situation. In the era of the Great Leap Forward, starting in 1958, the administrative authority of many higher education institutions was delegated to local governments and each provincial government established a comprehensive university as the center of each province. This aimed to promote the expansion of higher education opportunities. With the Great Cultural

Revolution, starting in 1966, the idea of “class struggle” was brought into universities; many university teachers and intellectuals were sent to re-education institutions in rural areas. As in Soviet Union-style higher education, Chinese education reform, which had emphasized “expertize” in the 1950s, was now totally denied. Instead, the government promoted higher education institutions that could provide curriculum and educational activities aiming to lead to greater labor productivity (Zhang, 2009; Otsuka, 1996).

In 1978, following the end of the Cultural Revolution, it was declared at the National Education Conference that the goal of educational development was to develop the human resources necessary for the “modernization” of the country. Disciplines deemed necessary for economic construction were expanded, in contrast to the previous “Science and Engineering centered” system. Adult higher education institutions, a self-study examination system, and satellite TV education were developed—aiming to accommodate the demand for higher education among those who were unable to go to universities and colleges during the Cultural Revolution. In 1978, the “key university” system with direct and prioritized control and support by the central government was also reopened (Nanbu, 2009).

It should be noted that, throughout the Cold War and in mainland China under the communist regime, universities and academic activities were conducted in Chinese. This also applies to Taiwan, which was under the *Kuomintang* (KMT; National Party) administration. Taiwan’s higher education was affected by the United States and other pre-war Chinese universities under the control of the KMT, the post-war US influence, and the long-standing influence of Japanese colonial control (Hou et al., 2021). As indicated by Wu et al. (1989), Taiwan’s citizens did not understand Chinese (Mandarin); directly after their return to China, they required extensive tutoring to learn the Mandarin required for study at Chinese universities. Yet, according to Ogawa and Nanbu (2008), Taiwan’s education system after 1950—under the administration of Chiang Kai-shek—had basic features such as a centralized education system, the usage of Mandarin (national language), and the “Three Principles of the People” of Sun Yat-sen. There was powerful government control over management and operation, including student recruitment, rights of curriculum making, teacher recruitment, and personnel management. The authors also note that “university autonomy” and “academic freedom” were limited, under the state of emergency.

In Hong Kong, under UK control (and especially at the Chinese University of Hong Kong, where the medium of instruction was Chinese)—as well as in Singapore, where Nanyang University existed temporarily—countries and administrative areas with large Chinese diaspora communities sought to construct Chinese language-based universities.

Korea: challenge to its unique identity

In the 19th century, the Korean Peninsula was under the control of the Joseon Dynasty. The Korean Empire was established as a modern nation-state in 1897, although it was soon merged with Japan in 1910. After World War II, the Korean War resulted in the territory’s separation into the Republic of Korea and the Democratic People’s Republic of Korea. Both countries have developed universities and higher education systems. Given the limitations on literature from North Korea, this paper focuses only on South Korea.

Umakoshi (1995) found that the development of the modern university concept in the Korean Peninsula—from the Joseon Dynasty of the enlightenment period, to the Japanese regime, and up to the modern period through the US military administration—was a history created by the Korean acceptance and resistance of external factors. These include the influences of the Qing Dynasty (China), Japan, and the United States; and the exploration of a unique identity for Korea.

Sungkyunkwan has a long history from the end of 14th century in taking responsibility for fostering bureaucracy—based on the imperial examination system, starting in the Korea Dynasty. In the enlightenment period of the 19th century, this institution transformed itself into one that taught the “new modern subjects,” such as geography and arithmetic. After Korea was colonized by Japan in 1910, Sungkyunkwan was reorganized into an academic research institute and focused on the study of Confucianism. There were also many traditional Korean private schools and modern private schools, many of which had been established by Christian missionaries from the United States and Europe. The Japanese colonizers adopted a policy of restraining the establishment of higher education institutions in Korean Peninsula. There were only two officially designated professional colleges: Yonhi College, which later became Yonsei University; and Busong College, which later became Korea University. Apart from Keijo Imperial University, no other university was established in Korea until the end of its post-war liberation (Kim, 2018a). In the interim, there was a spread of Korean-medium education and knowledge production in Korean language inside and outside of Korea. For example, Christian missionaries privately published Hangul-language books; these later became the foundation for Korean Studies in Europe and the United States (Asami and An, 2012).

Keijo Imperial University was the only *Daigaku* (university) on the Korean Peninsula, under Japanese occupation. Based on Japan’s policy principle of “Integration of Korea and Japan,” the educational curriculum—as well as the faculty members and teaching language (Japanese)—were all transplanted from Japan. Opportunities for higher education were extremely limited, as the share of Korean students at the Keijo Imperial Universities was 40% in maximum (Umakoshi, 1995).

After the founding of the Republic of Korea in 1948, an educational law was enacted in 1949 under the Rhee Syngman administration. The law clearly stipulates the development of “the spirit of patriotism” and the “succession and uplifting of ethnic culture,” as the national educational policy. The Keijo Imperial University was officially abolished and reconstructed into the Seoul National University (*Seoul Daehakgyo* 서울대학교), by integrating it with several former governmental professional colleges. The first president of Seoul National University was Harry B. Ansted, an American. In the process of “De-Japanization”, exchanges of faculty members and financial supports mainly from the US were implemented; many faculty members had received their degrees in the US. As a result, South Korea’s own universities were formed under the influence of the US system of higher education.

Meanwhile, one out of every four Korean graduates of Keijo Imperial University became a university professor (Jung, 2002) after the liberation, and Japanese literature was widely read until around 1970 (Kim, 2018b).

Along with the 4-year comprehensive universities, with their various faculties, a number of colleges were established to focus on single disciplines. Due to the demands of industry and to Koreans' strong aspirations for higher learning, many colleges became comprehensive universities in the 1980s as part of the process of providing mass higher education. Vocational schools were also upgraded to junior colleges and industrial universities. Many of these 2–4-year junior colleges and industrial universities have now been officially named *Daehakgyo* (universities).

Importantly, Korea's Constitution Revision of 1987 included a guarantee of universities' autonomy. Based on Article 9 of the Fundamental Law of Education, Article 28 of the Higher Education Act implemented in 1998 defines the purpose of the university as: "(to) foster a good personality, to contribute to the nation and human society by teaching and studying deep academic theories and their application methods necessary for the development of the nation and human society." Under this law, in addition to its (regular) universities, South Korea offers industrial universities, education universities, junior colleges, distance universities, and technical universities. Graduate schools have been classified into three categories: (1) general graduate schools for academic research and major educational purposes; (2) professional graduate schools providing the practical theory, research, and development required for the cultivation of human resources in professional fields; and (3) special graduate schools, whose main purpose is to offer vocational and continuing education.

Transformation of the concept of "university" in East Asia through globalization (1990s–present)

This article analyzes two time periods: before and after the end of the Cold War. According to Zhong (2018), this division of time periods corresponds to the rise of the neo-liberal alternative, which shifted thinking away from modernization as the premise of the nation-state and away from the theory of development. During the period of globalization after the Cold War, there were structural changes in higher education in Asia. Many Asians studied at US universities, then returned to Asia as faculty members. There was also an expansion of the international academic network, in which English was accepted as a common language. The structural changes can be summarized as below.

First, exchanges between China and the western world have significantly expanded. China's shift to reform and to opening up, starting at the end of the 1970s; its introduction of the market economy; and its restoration of diplomatic relations with the United States and Japan have all served to rapidly expand mutual understanding and networking between China and the West, including the promotion of study abroad and research exchanges. Ever-increasing globalization, after the collapse of the Soviet Union, has also led to a significant integration between the socialist and capitalist spheres—albeit with many twists and turns along the way.

Second, and in connection with the above, the concept of "East Asian models" for universities and higher education became crystalized. The World Bank (1993) reported that the role of education in human resource training was an important factor in social and economic development in the region, based on its analysis of Japan and of New Industrial Economies (NIEs) like South Korea and Taiwan. In Japan, research around the key features of the country's universities and education also progressed. Significant progress was likewise made, in research unveiling the common characteristics of higher education across East Asia. These include the value placed on a hierarchical system of higher education; and the high levels of investments made, along with the high value placed on educational qualifications, by families and by society at large (for example, Marginson et al., 2011).

Third, there has been a change to the prestige structure of universities in East Asia. Japan's top universities received world-wide attention at a very early stage and built dominant positions in Asia in the late 1990s. Universities in Hong Kong, South Korea, Taiwan, Singapore, and mainland China have subsequently risen rapidly in various types of university rankings. Conversely, Japanese universities have recently received less positive attention, against a backdrop of stagnant investment in higher education and delays in internationalization (Yonezawa, 2021).

Fourth, the social system has changed in East Asian countries and administrative regions, impacting higher education. Since the late 1980s, the democratization of Korea has had a major impact on expanding its higher education opportunities and systemic flexibility. Taiwan and Japan have also experienced changes in government, provoking a reconsideration of each country's path toward increased higher education opportunities. With the handing-over of Hong Kong and Macau to China, opportunities for higher education have expanded and educational systems and curriculum have changed.

Japan: growing interest in Asia

Against the background of changes in its economic growth and international situation, Japan has actively taken initiatives to internationalize higher education. The government launched a plan to accept 100,000 international students in 1983 and 300,000 international students in 2008, which was realized in 2019, just before the sustain of student mobility by the Covid-19 from 2020. To boost the international competitiveness of Japanese universities around science and technology, Japan has enacted the Basic Act of Science and Technology and promoted a project for capacity development at its research universities. The country's national and local public universities were incorporated in 2004. In 2013, the Japanese government set a policy goal to ensure that 10 Japanese universities were ranked among the top 100 in the world; this Top Global Universities project is being promoted as a 10-year project until 2023. Under the Democratic Party of Japan, from 2009 to 2012—proposed the joint promotion of quality assurance and student exchanges between Japan, Korea, and China. This Campus Asia project was later developed as part of the Inter-

University Exchange Project by the Japanese government, aiming at strategic cooperation with various countries and regions of the world. Yet Campus Asia, at present, does not function—in concept or in practice—as a framework for regional Higher Education, as does the European Higher Education Arena, while the efforts to develop regional higher education consortium covering East Asia and South East Asia are ongoing.

Japan's legal definition of a university remains as stated before in the School Education Law. However, the revision of the Fundamental Law of Education in 2006 included a new legal definition of “university”: “University as a center of academia would cultivate well-educated people and professional ability as well as creating new knowledge and, through providing these outcomes to the society, eventually contribute to the society” (Chapter 7 Article). Here, in addition to the functions of academic development and cultivating individuals, the university's relationship and contribution to society is given more emphasis.

Amid the process of transforming Japanese universities, there is a growing interest in Asian higher education—both in the region and in the world. Since the start of the 21st century, Japan has also begun to actively reference the higher education policies and practices carried out by its Asian neighbors (Jung et al., 2018).

China (greater China): challenge to the “world class”

In 1985, China announced the “Chinese Communist Party's Decision on Education System Reform.” The diversification of higher education institutions was implemented, and the main administrative system for universities shifted from the national level to the local level. The management autonomy of higher education institutions was also expanded; their capacity to adapt to the needs of economy and society was strengthened; private capital began to be permitted in higher education sector; the university curriculum was reformed; and teaching methods and promotion of research, based on “the president responsibility system,” were promoted. The expansion of exchanges with the United States and other Western countries has had a significant impact on the debate around the role of universities (Kaneko and Xu, 2006; Yang, 2003). In the 1990s, as part of “college and department adjustment,” specialized universities were merged and the establishment of comprehensive universities was promoted. In 1993, the central government launched the “211 project,” a policy of building key universities and key departments. It aimed at building 100 world-class universities over the 21st century. In 1998, the “985 Project” was announced. The project concentrates resources and investments on a smaller number of top universities, aiming to establish them as world-class (Huang, 2005; Yang, 2003). In 2017, the government launched a further policy: the “Double world-class university” project aims to build both world-class universities and world-class specialized fields (Yonezawa and Huang, 2021).

Simultaneously, the government is consistently making efforts to expand higher education opportunities and narrow regional disparities; collaboration with overseas universities and the inbound and outbound exchange of students are also being actively promoted. Chinese universities are also actively taking initiatives toward international expansion—such as the Confucius Institutes, which were undertaken through collaboration with universities. There is also the Belt and Road Initiative, linking China and the world through international cooperation (Jiang and Zhang, 2017).

International expansion and structural changes are also progressing in the Greater China region. In Taiwan, from 2011, the acceptance of a limited number of students from mainland China has been initiated (Wang, 2013). Universities in Hong Kong have also matched China's standards, to change their undergraduate programs from three years to four years. They have also introduced liberal arts education for the first year of undergraduate programs, per the advice of experts from American liberal arts colleges (Mok and Cheung, 2011). In China, “Shuyuan,” which is derived from the Confucian tradition, has been newly established; the initiative aims to develop a specific general education that was originally born in China. In addition, Chinese universities have developed branch campuses and programs in Southeast Asia, especially in places like Singapore and Malaysia that host a large Chinese diaspora. An exploration of the identity of Chinese universities and higher education—allowing for such innovations as “hybrid” universities, which are formulated through the mutual impact between the East and the West and apply an independent methodology—is not limited to the domestic level. Such explorations are also being developed at the global and Asian regional levels (Yan, 2016).

Still, “university” is not yet clearly defined in China's amended Higher Education Act of 2015. Moreover, its dual governance system—in which the University of China's Principal (President) and the Party Secretary share this responsibility—is maintained (CCP and the State Council, 2017). Furthermore, in the Greater China region, universities coexist with each other while maintaining diversity in a number of different political, social systems, and higher education systems (Lo, 2016).

Korea: active ambition toward globalization

Under Park Chung-hee's administration, South Korea's universities were controlled as institutions for nationalism and anti-communism. In the 1980—with the massification of higher education and social democratization—there was a diversification and expansion of higher education institutions, including the establishment of new universities and the upgrading of colleges to universities. Open universities were also established and educational universities were promoted to become four-year universities. Kim Young-sam's administration later launched the Korean version of globalization. During Kim Dae-jung's administration, the government implemented the Brain Korea 21 (BK21) Project. This aimed to build a high-quality human resources training system, by creating both world-class research-focused universities and universities with local characteristics. In recognition of the success of BK21 in terms of global competitiveness, the second stage of BK21 continued even under Roh Moo-hyun's administration.

Korea's dependence on overseas contacts (particularly in the United States) to foster researchers for the top universities has continued. Yet this also links Korean researchers with an international knowledge network (Yonezawa et al., 2016). The Korea Project has been implemented, aiming to accept international students and thus aid in the international dissemination of Korean studies and civilization. The project includes graduate schools for international studies, which carry out education and research in English; undergraduate programs, which are modeled after the liberal arts colleges of the United States; and education programs that allow international students to conduct research on Korean Studies in the Korean language (Shimauchi, 2016). Korea's presence in Asia has been strengthened—when it comes to both research and the meaningful exchange of experts, researchers, and students.

Conclusion and discussion

In East Asian universities and societies, the transmission, consolidation, and sharing of knowledge through translation have been implemented in patterns that are very different from those in medieval Europe (with Latin as the lingua franca) or in contemporary Europe (with English as a globally shared academic language). Modern universities in East Asia were established in close relation with each country's nation-building activities, and in line with a frequently changing hegemonic power context and geopolitics. The languages in use, and the patterns of translation, are closely connected to national identity—which also appears in the concepts and identities developed around universities in the region.

Under these diverse and dynamic conditions, East Asian societies have not yet been successful in forming a common understanding of the concepts and identities surrounding their own universities. There are always concerns over issues being “lost in translation”—which may lead to miscomprehension around the essential characteristics of universities, such as academic freedom and universities' autonomy.

In this context, it would be naïve to expect a seamless and straightforward transformation of the missions of East Asia's universities—from the nation-building of the past, toward a much-needed worldwide collaboration to tackle the global challenges of the present and future.

Let us recall that universities once closed, under the French Revolution—a fact that dramatically impacted the country for generations. History indicates that a national demand for science and technology, and for the development of high-skilled human resources, does not always result in supportive attitudes toward universities as autonomous academic communities. The global development of universities has stimulated an “arms race in knowledge,” and the close link between national governments and industry has tended to strongly link academic exchange and collaboration with national interests. Even in Japan—where the national constitution guarantees academic freedom—legal actions to limit international collaboration with researchers from specific countries are not uncommon.

The time has come for universities around the world to initiate mutual dialogs, once again seeking a common idea of a university in the contemporary context. These dialogs must be based not on a center-periphery structure, but on a mutual respect for diversity and on the need to address common global and regional challenges—challenges that are fast becoming impossible to ignore. Dialogs around today's idea of universities could be linked with postcolonial discourses. Yet, more importantly, they should be led by academics—across nations and institutions—who engage in self-reflection. Universities around the world can share an effective and meaningful common identity, in future, only if academics exert a strong will to create such an identity today.

Economic analyses of investments in and returns on higher education are rooted in [Becker's \(2009\)](#) human capital framework. The central theme of human capital is that members of the labor force can acquire knowledge and skills by attending school or engaging in on-the-job training, and these investments lead to benefits. As such, students, corporations, and society weigh the costs and benefits of potential investments in higher education before making investment decisions. These decisions, in turn, shape how higher education is financed.

In many countries around the world, higher education is financed by a mixture of public and private sources. Through tax benefits and direct funding to institutions, and financial aid to students, public funding covers a substantial proportion of the costs of higher education. However, over the last 30 years or so, the private portion of costs in the form of tuition and fees has been on the rise in many countries, coinciding with increasing private returns of higher education. Recent decades have also witnessed the rise of corporate funding of academic research and grants for students. Using human capital as a backdrop, this article describes the economic impacts of higher education on students, corporations, and society with a focus on economic benefits rather than costs. Whereas higher education yields both economic and non-economic benefits, most researchers who have assessed the impacts of higher education have focused on more quantifiable economic benefits. The same caveat applies here.

The basic premise of human capital theory is that students and their families weigh the costs and benefits of potential investments in higher education before they make enrollment decisions. Economic costs for individuals include tuition and fees, books, room and board, as well as potential earnings foregone while attending college. Economic benefits for individuals accrue primarily in the form of earnings increases associated with higher education. While the cost side is relatively straightforward, the benefit side is much more complicated because (a) it occurs over one's lifetime; (b) the causal effect is difficult to measure; and (c) considerable variations exist across institutions, majors, and individual characteristics. These variations are discussed in this article.

Research and knowledge generation is another important function of higher education. Traditionally, research and knowledge was viewed primarily as a public good. For example, the federal government has played a dominant role in supporting research and development in the United States. Increasingly, however, research and knowledge are construed as private goods and higher education is shifting from a "public good knowledge regime" to an "academic capitalist knowledge regime" ([Slaughter and Rhoades, 2004](#), p. 28). As public funding for higher education has stagnated or declined in recent decades, corporate funding for academic research has increased globally, which has facilitated the commercialization of academic research while raising considerable concerns about academic freedom.

Higher education benefits not only individuals, but also society at large. Higher education institutions and the research they produce contribute to economic development at the societal level. College graduates pay higher taxes on higher earnings; they are also less likely to rely on government programs (e.g., health care, social security) or to be incarcerated. Because higher education is considered a public good, the level of demand for higher education by individual students in the absence of public funding would be less than optimal from a social perspective.

This article provides an overview of the economic impact of higher education on students, corporations, and society. Among these three subjects, the economic impact on students has been studied most extensively; thus variations across a range of factors including undergraduate majors, institutions, gender, and race/ethnicity are also discussed. While this article draws on empirical findings from a wide range of countries, the majority of studies included are based on data from the United States and OECD countries. Finally, education systems around the world use different terminologies (e.g., higher education, college, university, undergraduate, etc.) to describe postsecondary education; these terms are used interchangeably in this article.

Impacts on students

Human capital theory posits that the decision to pursue a postsecondary degree is based on the comparison of individual costs and benefits. This section begins with a brief overview of the immediate and deferred costs incurred by university students and their families, proceeds to an account of earnings and employment premiums for university graduates coupled with estimates of private returns to higher education, and concludes with a discussion of institutional, academic, and demographic variation in the economic impacts of postsecondary education.

Analyses of the individual economic impacts of higher education are complicated by selection issues. Compared to their peers, students who enroll in an institution of higher education may be more academically prepared, have access to more financial resources, or have greater motivation and/or aptitude in skills tied to postsecondary success, all of which may contribute to later success in the labor market. Researchers have attempted to mitigate selection issues by using quasi-experimental methods or incorporating extensive statistical controls. The best available evidence indicates that university attendance has positive economic impacts for most students, with benefits outweighing costs across a wide range of national contexts, fields of study, and student demographics. However, evidence also indicates persistent racial, ethnic, and gender disparities in the economic outcomes of university graduates.

Costs

Tuition costs for university students vary widely around the globe. In a third of OECD countries, the costs of a bachelor's degree are covered by government subsidies and other revenue sources, with no tuition for students (OECD, 2020). Costs to students in the next third of countries are relatively low, averaging less than \$2000 USD per year, while at the high end, students in Chile, the United States, and the United Kingdom pay an average of \$8000–12,000 USD annually while enrolled in bachelor's degree programs at public (or, in the UK, government-dependent private) institutions. Tuition for independent private institutions is generally much higher than for public or government-dependent private institutions—approximately three times as much in Spain, Italy, and the United States. Tuition also can vary significantly by field; for example, average costs of a bachelor's degree in education typically are lower than the costs of a health degree in a given country (OECD, 2020). Beyond tuition and fees, students incur costs for room and board, which may increase the total cost of university attendance substantially.

Meanwhile, the total direct costs of higher education may be reduced for some students through grants and scholarships; during AY 2017–2018, students at four-year (i.e., bachelor's degree-granting) colleges and universities in the US received, on average, approximately \$13,000 in scholarship and grant aid from governmental or institutional sources (de Brey et al., 2021). The availability of scholarship and grant aid varies substantially across OECD countries and across US states and institutions, with some prioritizing scholarships based on academic qualifications (e.g., secondary grades and/or standardized test scores) and others directing more funds to need-based grant aid, eligibility for which is inversely related to a student's financial resources (NASSGAP, 2020; OECD, 2020).

Students and their families may defer some costs by taking out loans, especially if the costs of university attendance are substantial relative to their financial resources. Many OECD countries offer means-tested public student loans, while some countries (e.g. Chile, Japan, and South Korea) use academic achievement to determine loan eligibility (OECD, 2020). The issue of student borrowing remains especially prominent in the United States, where nearly all US students are eligible to borrow a government student loan and over three fifths of full-time students incur debt before completing a bachelor's degree, with average debt at bachelor's degree completion increasing precipitously during the 1990s and 2000s and plateauing at just under \$30,000 in current dollars between 2012 and 2016, the most recent year for which detailed data is available (de Brey et al., 2021; Schak et al., 2020).

Borrowing can be a strategic move to alleviate credit constraints facing many students and their families, deferring the costs of university attendance to later years when a student anticipates higher earnings. In the United States, where postsecondary costs are generally high, borrowing is a necessity for many students whose families have limited financial resources. However, student debt has negative ripple effects on borrowers' financial health, limiting flexibility and shaping future decision-making and economic opportunities (Elliott and Nam, 2013). For example, higher student debt negatively affects borrowers' credit scores and rates of home ownership, a key avenue of wealth-building (Mezza et al., 2020). The financial consequences are even greater for borrowers who are unable to repay their loans and default on them, an outcome that is much more common in the United States now than in previous generations, and which disproportionately affects Black and Hispanic/Latino/Latinx students, individuals from low-income families, and those who attend for-profit universities (Hillman, 2014; Schak et al., 2020).

Benefits

For individuals, the economic benefits of higher education are primarily in the form of higher earnings and higher likelihood of employment, along with other benefits such as increased occupational prestige and better health outcomes, which are partly linked to employment-based access to insurance (Mayhew et al., 2016; McMahon, 2009; OECD, 2020). A recent report from the OECD (2020) indicates that in 2019, the average employment rate across OECD countries for 25- to 34-year-olds with a tertiary education was 85% compared to 78% for those with an upper secondary or postsecondary non-tertiary education and 61% for those without upper secondary education. Substantial advantages in the likelihood of employment have also been observed in the United States (Ma et al., 2019) and South Africa, where the employment probability premium rose substantially between the mid-1990s and

2010 (Branson and Leibbrandt, 2013). Importantly, a direct comparison of employment outcomes cannot fully capture the impact of a university education on access to employment, because one cannot assume that university graduates, *if they had not attended university*, would have the same economic trajectory as those who actually did not attend, given potential differences in unobserved characteristics. Nevertheless, these comparisons confirm that individuals with higher educational attainment have greater access to employment and financial security, on average.

In addition to a higher likelihood of employment, university students earn more than their peers, on average, across a wide range of national contexts. In Latin America and the Caribbean, workers with a postsecondary degree enjoy monthly earnings that are, on average, double the earnings of those with only a secondary degree (Urzúa, 2017), similar to the earnings advantage for both men and women in South Africa (Branson and Leibbrandt, 2013). The OECD countries with the highest earnings premiums for postsecondary education are all in Latin America, namely Brazil, Chile, Colombia, and Costa Rica. Nonetheless, premiums are substantial across OECD countries, with a 54% average earnings advantage for full-time workers with a tertiary degree versus those with an upper secondary degree, and an earnings premium of at least 20% in every OECD country except Norway (OECD, 2020). Education-based earnings premiums tend to widen with increasing age and work experience (Branson and Leibbrandt, 2013; OECD, 2020; Ma et al., 2019), and for some graduates are partly explained by the fact that they work longer hours than their peers (Zhang, 2008).

One way of assessing whether the financial benefits of higher education outweigh the costs is to estimate the age at which the cumulative earnings of an average university graduate surpass those of an average secondary school graduate. Assuming that an individual who does not enroll in higher education would enter the workforce full-time at age 18, Ma et al. (2019) calculated that both associate's degree and bachelor's degree completers in the United States reach the break-even point in their mid-30s, slightly earlier for those attending lower-cost institutions or receiving more scholarship and grant aid, and slightly later for those who take longer to complete their degree.

Another way of quantifying the economic advantage of university attendance is the private internal rate of return (IRR), i.e., the rate at which the present value of costs associated with an investment equal the present value of benefits. A review of rigorous analyses from the 2000s suggests a rate of return of approximately 12–14% for a four-year university education in the United States (Mayhew et al., 2016), and that return likely has increased over time (Long, 2010). Toutkoushian et al. (2013), whose IRR analysis incorporated the risk of dropout (a fairly common outcome in the United States and many OECD countries) and variation in the timing of both dropout and graduation, estimated an IRR of 15% for bachelor's degree graduates at private colleges and universities and 20% for graduates of (less expensive) public colleges and universities in the United States. Both high-achieving students and students whose academic performance is marginal see substantial returns, with some evidence that returns for the latter group are similar to or greater than those for the former (Brand and Xie, 2010; Oreopoulos and Petronijevic, 2013).

Notably, the economic benefits associated with higher education are not exclusive to university graduates: students who attend university but do not complete a degree tend to have better economic outcomes than those who do not attend university at all. In the United States, workers who are 25 and older with some postsecondary experience but no degree average approximately 13% more in post-tax income compared to those with only a secondary school degree (Ma et al., 2019), with evidence of especially strong returns in less credential-intensive fields such as protective services (e.g., firefighting and law enforcement) and skilled trades (Bahr, 2019). Toutkoushian et al. (2013) estimated the private IRR for students who attend a four-year college or university but do not graduate at 4.3% or 5.4% for public and private institutions, respectively. University attendance without degree completion is similarly associated with positive returns across Latin America and the Caribbean, although as in the United States, the returns within each country are substantially lower for non-completers than for degree completers (Urzúa, 2017). On the other hand, incurring student debt without the higher payoff associated with degree completion can be a major financial liability, and non-completers in the United States experience student loan default at substantially higher rates than associate's or bachelor's degree graduates (Schak et al., 2020).

Variations in benefits across students

Despite increasing costs for many students, the economic benefits of higher education for individuals outweigh the costs, on average, across a wide range of contexts. Yet these benefits do not accrue equally to all, with substantial variations across fields of study and institutions, as well as racial/ethnic and gender-based disparities. Generally, the postsecondary earnings advantage is higher in fields such as science, engineering, and business, and lower in fields such as the humanities, arts, and education (OECD, 2020). In fact, Urzúa (2017) found negative returns for some education and humanities graduates in Chile and Peru, while a review of US-based analyses from the early 2000s shows that estimates of the earnings premium associated with majoring in STEM and health sciences fields versus majoring in education range from approximately 25%–55% (Mayhew et al., 2016). An analysis of highly educated urban workers in Asia found variation in field-specific earnings premiums by city, with a significant earnings advantage for both men and women with degrees in the natural sciences (vs. the humanities) in Seoul and Shanghai, but not in Jakarta, Kuala Lumpur, Delhi/Mumbai, Hanoi/Ho Chi Minh, or Bangkok (Takeuchi, 2021). Meanwhile, an analysis of university graduates in Ireland shows that field-specific returns to a university education are greater at the lower end of the earnings distribution (Kelly et al., 2010).

Institutional differences, including funding, prestige, and/or quality (often measured in terms of selectivity, entrance exam scores, or external ratings systems; Mayhew et al., 2016; Zhang and Thomas, 2005), also shape private returns to higher education in many countries. For example, researchers using methodologies allowing for causal inference (e.g., regression discontinuity and

propensity score analyses) have found that eligibility for or attendance at an elite university increases wages by 5–10% in both China (Jia and Li, 2021) and the UK (Chevalier, 2014). In the United States, the wage returns associated with postsecondary quality have increased over time, but the relationship between quality and earnings varies considerably by race, gender, and parental education, among other factors (Long, 2010; Mayhew et al., 2016; Zhang and Thomas, 2005). Additionally, graduates of elite universities in the United States tend to work longer hours and have lower job satisfaction than their peers once earnings are controlled (Liu et al., 2010; Zhang, 2008).

In many countries, gender disparities in earnings persist across all levels of educational attainment (Ma et al., 2019; OECD, 2020; Urzúa, 2017), and are partly driven by disparities in degree attainment in fields of study associated with more lucrative employment. However, there is some variation globally in gender-based returns to higher education. Across 18 countries in Latin America and the Caribbean, the average gender gap in the return on a higher education degree is 15% in favor of men, but country-specific gaps range widely, from 92% to 108% gaps in favor of men in Mexico and Guatemala, respectively, to a 54% gap in favor of women in the Dominican Republic (Urzúa, 2017). Women experience higher returns on postsecondary degree attainment in South Africa and in the United States (Branson and Leibbrandt, 2013; Mayhew et al., 2016).

Researchers have found substantial returns to higher education for marginalized racial/ethnic groups in South Africa and the United States (Branson and Leibbrandt, 2013; Ma et al., 2019). In the United States, within-race earnings advantages for Black and Hispanic university graduates (vs. secondary school graduates) are generally similar to those for white university graduates (Ma et al., 2019). Hispanic graduates of Hispanic Serving Institutions (HSIs) have outcomes similar to their peers at comparable non-HSIs (Park et al., 2018), while Black graduates of Historically Black Colleges and Universities (HBCUs) have stronger long-term labor market outcomes than non-HBCU graduates (Price et al., 2011). In South Africa, earnings premiums for Black African university graduates are lower than for the population as a whole, but have increased at a faster rate than the population average between the mid-1990s and 2010 (Branson and Leibbrandt, 2013).

Yet educational attainment alone cannot erase deep racial inequities in economic opportunity. In South Africa, there is evidence that racial gaps in likelihood of employment among university graduates are partially driven by systematic disparities in the institutions to which students have access, including disparities in institutional capacity and resources (van Broekhuizen, 2016). In the United States, Black and Hispanic men with bachelor's degrees have similar average earnings to white men with associate's degrees, and Black and Hispanic men with associate's degrees have similar earnings to white men with only a secondary education. Likewise, at every level of educational attainment white women have higher wages than their Black and Hispanic peers, although the magnitude of the disparity is less pronounced for women in part because the within-race gender pay gap is wider for white men and women than for other racial/ethnic groups (Ma et al., 2019).

Impacts on corporations

The proliferation of higher education, especially since WWII, has led to a larger percentage of the workforce graduating with degrees from post-secondary institutions. These graduates have significant impacts on the quality, composition, and culture of the corporate workforce. Furthermore, corporations continue to partner with universities and faculty to advance research and develop new technologies. This relationship between higher education and corporations continues to develop globally as investments in higher education are associated with expectations of positive impacts on corporations.

Skilled and diverse workforce

Productivity is a principal concern for corporations, as it is a significant driver of profit generation and cost advantages over competitors. Given the increasing pace of technological innovation, many workers globally and in the United States must pursue educational opportunities to address gaps in their skills. Firms are therefore incentivized to improve the human capital of the existing workforce, which can be accomplished by hiring new graduates or training existing employees. While some of the demand for reskilling can be filled internally through corporate learning and development programs, corporations often outsource training to higher education institutions. In a recent study, Osterman (2020) found that 56.5% of employees had received formal training from their employers during the previous 12 months, although employer investments in training varied greatly across firms and employees. For example, full-time employees with more education who worked in large firms were more likely to have received formal training, whereas racial minorities including African American, Hispanic, and Asian workers were less likely to receive employer investments in training. Corporations can also rely on higher education institutions to upskill their workers. Community colleges work closely with regional corporations and establish certificate programs to provide training and workforce development (Osterman, 2020). Within emerging markets, improvements in higher education quality has been linked to improved labor markets. One study suggested that large-scale reform to the Senegalese higher education sector led to a 9% increase in employment gain for younger, high-skilled workers relative to older workers (Boccanfuso et al., 2015). It is likely that some benefits of education are passed on directly to corporations. In China, one study estimated that an additional year of schooling raised the marginal output of a given firm by 31%, while the marginal increase to worker wage is far lower (Fleisher et al., 2011). As corporations in emerging markets demand newer skills to compete globally, higher education institutions in those countries will play a critical role to ensure graduates are equipped with the necessary skills to supply the workforce. In each of these cases, higher education institutions have developed symbiotic relationships with corporations to meet the demand for skilled labor.

Given the productivity benefits of hiring talented employees, corporations compete to attract skilled graduates in a variety of ways. In some instances, recruitment methods reflect potential employees' experiences at higher education institutions. One relatively new development in recruitment is an emphasis on Corporate Social Responsibility to attract the most qualified recent graduates. These initiatives are intended to demonstrate that a company's values match the values of talented graduates, who are significantly influenced by their experiences in higher education institutions. Indeed, several studies have demonstrated an increasing global prevalence of social responsibility within higher education curricula (Vázquez et al., 2013), which in turn has encouraged the promotion of Corporate Social Responsibility in the competition for talent. As student preferences and higher education curricula evolve, corporate recruiting strategies are likely to respond.

Research has demonstrated that diverse organizations lead to greater innovation and better respond to the demands of a diverse customer base (Hunt et al., 2018). It is therefore a critical function of higher education institutions to supply the labor market with a pool of talent that is both skilled and diverse. In the United States, there is strong evidence that lower socioeconomic status is associated with a lower likelihood of degree completion (Baker et al., 2018). The result therefore is a bias toward a relatively homogenous graduate labor force derived from higher socioeconomic status, which in turn increases social inequality. As a consequence, corporations have supported admissions policies that promote diversity, arguing that education within a diverse environment better prepares potential employees for work in a global environment (Fisher, 2013). Such practices will benefit corporations by increasing the diversity and global awareness of potential employees.

In the United States, higher education institutions play an important role in supplying a diverse composition of graduates to the labor market. In Europe, institutions have emphasized diversity as it relates to a wider variety of skills and competencies (Santoalha et al., 2018). State policies have been developed to ensure institutions are sufficiently different so as to provide the labor market with a diverse skill set. One example of this practice is a focus on creative human capital. International policies have articulated the importance of strengthening the interface between economics, culture, and technology, with a particular focus on services and creative content (UNDP, 2013). Historically, most creative graduates from higher education institutions have moved into arts and culture-related professions, but more recently creative degree programs have broadened to provide critical talent to the corporate world. In the UK, universities have emerged as creative knowledge centers within regional economies that provide creative human capital to local corporations. This has led to a correlation between a city's creativity and the number of creative graduates it employs (Comunian et al., 2015). In any country, having successful corporations across a variety of sectors requires a workforce with diverse skills. Higher education plays a critical role in supplying this workforce to corporations.

Strategic relationships

Corporations also have benefitted from higher education's pursuit of new knowledge by entering into strategic alliances with institutions. Such relationships are driven by opportunities to both reduce research development costs for institutions and increase the potential of technology transfer for corporations (Elmuti et al., 2005). Through strategic alliances, corporations provide funding for research and learning opportunities for students. As corporations continue to grapple with the rapidly accelerating complexity of technology, it is often beneficial from both a cost and innovation perspective to supplement their internal research and development with the faculty expertise and research infrastructure provided by universities. As these strategic relationships continue to grow, both corporations and universities will become more dependent on each other's resources. In the case of universities, private sources of funding will exert greater influence on the type of research produced, while corporations will become more reliant on external talent for research. Effectively managing these relationships will be a critical factor for corporations to remain competitive.

The presence of higher education institutions has been shown to influence the locations of new and regional corporate offices due to "spillover" effects of knowledge production and human capital in regions surrounding universities (Acosta et al., 2011). Although much produced knowledge is widely published, closeness, proximity to the knowledge source can provide additional access to a given field of research. This access is especially important in new, complex technological fields where gaps between commercial knowledge and academic knowledge are widest. Furthermore, strategic partnerships between universities and corporations hold great potential to facilitate knowledge production. In addition to knowledge, graduates, who constitute a form of human capital, are likely to remain in closeness, proximity to a given university. These graduates not only supply talent to nearby corporations, but also can serve as a channel for disseminating knowledge. Corporations or new businesses are incentivized to establish locations in closeness, proximity to universities to absorb either the knowledge produced through strategic relationships or human capital by recruiting recent graduates.

Future research

In general, there is limited research on the quantitative economic impacts of higher education on corporations, particularly at the macro level. While there is substantial research linking diverse workforces to improved productivity and innovation, there is limited quantitative research linking the effect to improved diversity within higher education. Furthermore, given the opacity of strategic relationships between higher education institutions and corporations, there is limited research on the economic value created by such arrangements. Future lines of inquiry could attempt to quantify the return on investment for corporations or estimate the economic value of technology transfers or spillover effects.

Impacts on society

Higher education's contributions to social, economic, and cultural development are often referred to as "public goods," and serve as the primary justification for public support of institutions. Scholars point to the development of land grant colleges in the United States and more recent efforts in Europe and Africa as examples of intentional efforts to align higher education with the economic interests of nation-states (Compagnucci and Spigarelli, 2020; Hazelkorn and Gibson, 2019), although many social benefits also accrue through the production of knowledge and technology.

As investments in higher education grow, institutions around the globe are facing increasing demands for accountability to demonstrate the efficient use of funds and high quality outcomes. According to the UNESCO Institute for Statistics (2020), the average government expenditure on education in 2017 was 4.5% of GDP, with rates ranging from 1.5% to 7.9% globally. Some argue that social benefits constitute nearly half of higher education's overall benefits (Trostel, 2015); however, measuring them can be challenging.

Three main approaches have been used to measure the social benefits of higher education: the social rate of return, the national income growth model, and economic impact studies. First, the *social rate of return* (SRR) examines the discounted future earnings of graduates (before taxes) compared to the sum of the private costs and public investments in higher education. Because SRR includes both private and public expenditures on higher education, it is often estimated at a lower rate than the individual rate of return. In the United States, SRR estimates range from 11.6% to 12.1%, with remarkable stability over time (Leslie and Brinkman, 1988; McMahon, 2009). Graduates of bachelor's degree programs in the United States contribute approximately \$381,000 more in taxes than the associated government expenditures, including public subsidies and financial aid (APLU, 2016). A decennial review of global literature (Psacharopoulos and Patrinos, 2018) notes that the "social returns follow the well-known pattern of falling by level of development and level of education" (p. 453), with post-2000 social rates of return for higher education averaging 10.6% overall and 16.4% in developing countries, particularly in Africa where the social rate of return to higher education is 20–35% in some regions. Whereas the SRR is an easy way to calculate the social benefits of higher education, it fails to take into account important benefits beyond graduate salaries and therefore tends to underestimate overall social benefits.

A second common approach to quantifying the social benefits of higher education is the *national income growth* model, which involves examining the portion of national economic growth attributable to higher education based on land, labor, capital, and the "famous residual," which is the unexplained portion of growth considered attributable to knowledge and technology generated by university research. The dynamic growth model suggests that each new phase of social benefits builds upon previous social gains. Subsequently, the benefits of higher education accumulate over time, with up to a 20-year lag between investment and the realization of external benefits. Studies based on this approach have revealed that education contributes to approximately 15–20% of income growth, and about a quarter of this contribution can be attributed specifically to higher education (McMahon, 2009). More recent research specific to Central China shows education overall contributed 23–29% to the GDP depending on province from 2003 to 2014, with higher education contributing less than 5% across all six provinces (Zhu et al., 2018).

Higher education's social benefits also can be estimated in *economic impact studies*. The most common economic impact studies take the economic base approach, focused on business volume and job creation at the local level. A multiplier is extracted to reflect the amount of economic activity generated by higher education expenditures. Estimates from studies in the United States yield a multiplier of approximately 1.6 per dollar of operating budget and a job creation rate of 59 jobs per \$1 million spent (McMahon, 2009). In European countries, these studies most often take the form of input-output models with Type I multipliers indicating direct and indirect effects, and Type II multipliers indicating direct, indirect, and induced effects. Studies have yielded Type I multipliers close to 1.3 and Type II multipliers close to 3 in the United Kingdom (Hermannsson et al., 2015; Zhang et al., 2017).

Taking a different economic impact approach, a study of data from 78 countries found that an increase in the number of universities between 1950 and 2010 was positively associated with the future growth of GDP per capita, with the strongest associations at the subnational level including spillover effects from nearby regions (Valero and Van Reenen, 2016). Recognizing that universities vary in size and quality, a separate study of universities in 169 countries between 1996 and 2013 used research output as a proxy for quality and found a positive impact on economic growth in both developed and developing countries, with the strongest effects in developed countries (Solarin and Yen 2016).

In an effort to leverage anticipated economic impacts, some regions across the globe have implemented place-making (aka precinct-development) strategies using institutions of higher education as community anchors based on the triple helix model of government-industry-university. Knowledge and innovation precincts are more prominent in centrally located cities with greater density of higher education institutions such as Barcelona, Helsinki, New York, Sydney & Singapore (Pancholi et al., 2018), though recent research examines the potential and unique challenges of similar place-making attempts in less dense regions and towns such as Iceland (Yigitcanlar et al., 2017). Given the evolution of these strategies over the last two decades, much of the literature is qualitative in nature, but evidence suggests universities can play a central and significant role in knowledge based urban and regional development (Yigitcanlar et al., 2017) leading to increased attention to this strategy by government and funders alike across the globe including in South Africa where the Ford Foundation has supported university city-building efforts (Bank, 2018).

Although the aforementioned methods enable social benefits to be quantified in relation to outputs, separate lines of inquiry have explored the non-market social benefits of higher education. Some have conceptualized this difference in benefit measures as a utilitarian view, exemplified by the previous three methods, versus a focus on the broader societal contributions of higher education (Hazelkorn and Gibson, 2019; Schofer et al., 2021; Trostel, 2015). Non-market benefits related to democratization and equity highlight the social benefits of higher education at a societal level. Democratization includes fair elections, lack of

domination, the right to organize opposition parties, and similar characteristics (McMahon, 2009), and relies on the training of legal and political leaders and an educated citizenry who can turn opinions into shared action and organizational structures (Schofer et al., 2021). The critical thinking and global/cultural awareness associated with higher education further supports human rights and social movements to address issues of equality and equity (McMahon, 2009). These societal benefits can present both a challenge and benefit to industry, where human rights campaigns may protect vulnerable workers thereby slowing and/or increasing the cost of economic growth while equal opportunity and treatment may increase productivity (Schofer et al., 2021).

Aside from the traditional question of how to measure concepts such as democratization and globalization, there is also the question of how to address the interdependence and multi-directional flow between higher education and associated social benefits (McCowan, 2018). Additionally, not all individual benefits can be aggregated, and most social benefits cannot be neatly disaggregated (Schofer et al., 2021). Finally, an omnipresent question remains internationally about whether higher education is an engine of social mobility or if it simultaneously perpetuates stratification and inequality.

Introduction

The sector of higher education and research has undergone a fundamental transformation over the past three decades. Academic capitalism and market thinking have become central features of the sector. Emerging in the wake of New Public Management (NPM) in the anglophone world of higher education they have spread all around the world to build “varieties” of academic capitalism and market thinking (cf. Schulze-Cleven and Olson, 2017). “Academic capitalism” means understanding universities as enterprises which compete for the ongoing accumulation of economic and symbolic capital. Economic capital comprises research funding, tuition, sponsors, scholars, and talented students. Symbolic capital includes prizes, honors, memberships in prestigious associations, citations, generally: prestige. At the macro level, this competition overrides competition for the best possible education and research. Without a competitive order, this competition tends to lead to the formation of oligopolies and an increasing gap between elite and rank-and-file universities in higher education and research on the macro level of the academic field. Elite and rank-and-file universities are therefore differently affected by academic capitalism. Therefore, they differ in their strategies of coping with competition on the macro, meso and micro levels. While elite universities dispose of great autonomy in defining their mission on the macro level and how to implement it on the meso and micro levels, non-elite universities are much more compelled to meet the prevailing expectations on the macro level and to turn them into the closely controlling management of research and teaching on the meso level and socialization of junior scientists on the micro level. In this chapter, we outline the state of research on the three levels of academic structural change in the context of spreading academic capitalism and market thinking as well as the different strategies of elite and non-elite universities to cope with increased competition for the accumulation of economic and symbolic capital. The focus is on the question of what effect this structural change has on the promotion of the best possible education and particularly knowledge advancement. We primarily deal with research because it is at the center of academic capitalism and therefore the primary topic of the respective literature. Nevertheless, teaching is part of this new feature of higher education institutions. With regard to research, universities are in permanent competition for the accumulation of economic and symbolic capital through raising funds, recruiting staff, commercializing findings through patents and disseminating expert knowledge. With regard to teaching, they compete for earning tuition fees, enrolling the brightest students, attracting foreign students as “cash cows” (Cantwell, 2015a), granting certificates for highest possible tuition fees, employing cheap part-time contingent faculty doing the job of undergraduate instruction, and placing graduates on the labor market.

Macro level: the superimposition of institutional competition for the accumulation of economic and symbolic capital on individual competition for progress of knowledge and recognition

Academic capitalism and market thinking at the macro level of the academic field turn universities into enterprises. Consequently, they superimpose competition between universities for the accumulation of economic and symbolic capital on competition

between scholars for best possible teaching and knowledge growth. With the accumulation of competitive advantages based on previous competitive advantages, this competition results in oligopolistic structures of knowledge production and knowledge transfer, privileging elite universities and disadvantaging non-elite universities.

The entrepreneurial university

Owen-Smith (2003) has observed increasing linkage of academic and commercial achievement at the most research-intensive US universities. In the knowledge economy, universities play a central role in generating economic growth. They are the dynamic force in the innovation network of science, business, and politics (cf. Jessop, 2017). According to Gibbons et al. (1994), this is mode 2 of knowledge production, where basic and applied research are not separated as in mode 1 but are closely intertwined. Etzkowitz (2003) and Etzkowitz and Zhou (2017) have coined this new mode of knowledge production the “triple helix of science, business, and innovation policy” (cf. Leydesdorff, 2012, 2018). According to Berman (2012), universities have become “economic engines” in this context by being able to retain ownership of patents generated with federal funds under the US Congress’ Bayh-Dole Act of 1980 (cf. Holloway and Herder, 2019; Shibayana et al., 2012). Strategic collaborations between universities and companies play a significant role. One basis for such collaborations is interlocking board memberships (Slaughter et al., 2014). Slaughter and Leslie (1997) and Slaughter and Rhoades (2004) have coined the term “academic capitalism” to describe this arrangement. According to Slaughter and Rhoades (2004: 1–34), academic capitalism manifests itself (1) in a close intertwining of knowledge generation with the production of economic goods, as seen in universities’ efforts to generate patents and copyrights of teaching materials; (2) in interstitial organizations such as technology transfer offices or intellectual copyright offices which directly link the university to the business world; (3) in the emergence of intermediate organizations such as the Association of University Technology Managers (AUTM) or the Business Higher Education Forum in the United States which mediate between academia and industry/business; (4) in the development of universities’ managerial capacity and internal control capabilities over their business processes that increase their strategic capabilities to position themselves in the competition for funding, acknowledgment, visibility, and market power.

In this process, universities are turned into businesses that aim at increasing their resources and translate them into economic as well as symbolic profits. Resources and reputation are multiplied in a spiraling accumulation process (Cantwell, 2016). Competition between universities for the accumulation of economic and symbolic capital increasingly overlaps with competition between researchers for the advancement of knowledge and recognition granted for contributions to knowledge growth by the scientific community (cf. Musselin, 2018; Pederzini, 2018). While in the latter competition the norms of collegiality and disinterestedness, as well as intellectual communism, as defined by Merton (1973 [1942]), ensure that the successful researchers do not completely crowd out the less successful ones, in academic capitalism there are no such barriers and there is cut-throat competition between universities aimed at recruiting outstanding scholars and the best students. There is a brain gain at the top and a brain drain across the board (cf. Khan, 2021). According to the Matthew effect (Merton, 1968), the winners enter an upward spiral by converting existing competitive advantage into further competitive advantage, while the losers continue to lose resources and reputation (cf. Cantwell and Marginson, 2018). This is why Clark (1998) was able to observe, as a matter of course, that universities which adopted an entrepreneurial strategy early on excelled in accumulating economic and symbolic capital compared to other universities (cf. Cantwell, 2016; Geiger, 2004; Rikap and Harari-Kermadec, 2020). Competitive advantages are concentrated at the top. Therefore, copying success models—for example investments in technology transfer centers—by rank-and-file universities often turns out to be a flop because the necessary resources in terms of economic and symbolic capital and a potent industrial environment in the neighborhood are lacking.

The concentration of resources on a small circle of top scientists also involves a growing number of people doing research and teaching under the direction of these “capital owners” and/or replacing them in teaching by contingent faculty on temporary contract. The result is a rising number of researchers and teachers who constitute a new academic proletariat. They are exploited to help produce all those merits which are appropriated by the capital owners (cf. McCarthy et al., 2017; Reay, 2014; Wheaton, 2020).

Protagonists of market thinking in higher education mostly think of ideal markets where equal conditions apply to every participant in the competition. This is, however, not the reality of higher-education markets. The market is widely shaped by inequalities of market power. To address this distorted nature of markets in higher education, a conflict-theoretical analysis of academic capitalism is called for. Most appropriate is drawing on Bourdieu’s theory of the academic field, academic habitus formation, academic capital accumulation and the embedding of the academic field in the field of power (cf. Bourdieu, 1975, 1988, 1996; Collyer, 2015; Mendoza et al., 2012; Münch, 2014; Beyer, 2021; Wieczorek et al., 2017; Wieczorek, 2021).

Oligopolistic structures of knowledge production

The result of the cutthroat competition unleashed by academic capitalism throughout the academic field are oligopoly structures that steer the knowledge process in the direction set by the successful elite universities and the so-called high impact journals that are closely intertwined with them through editors and authors (Hodgson and Rothman, 1999). The academic field is differentiated worldwide into a center occupied significantly by the US elite universities, a semi-periphery of older European and younger East Asian universities, and a periphery of universities in emerging and developing countries (cf. Beyer, 2021; Münch, 2014, pp. 13–37; Münch and Schäfer, 2014; Paasi, 2015). One consequence of the oligopolistic structure of the academic field is overinvesting

attention, recognition, and resources at the top while underinvesting across the board. The academically rich get richer, while the academically more modestly endowed stagnate in their resources or become even poorer (cf. [Mendoza et al., 2012](#)). An inverted u-shaped curvilinear relationship emerges between the investment of research funds and returns, measured in terms of publications and the progress of knowledge reported therein. That is, beyond an optimal mean endowment of research funds, a decreasing marginal utility of each additional amount of money invested is observed. Beyond the optimum, coordination expenses and administrative tasks grow to such an extent that they divert too much attention from actual research ([Münch, 2014](#), pp. 223–233; [Münch and Baier, 2012](#)).

In a purely economic sense, this is an inefficient allocation of research funds. The oligopolistically structured field allows members of the oligopoly to extract monopoly rents from their position. Monopoly rents are extra revenues in terms of economic and symbolic capital, generated through a monopoly position, in excess to the revenues which would be possible under perfect market competition (cf. [Welsh, 2021](#)). Two mechanisms of elite formation identified by [Burris \(2004\)](#) following [Weber \(1976, pp. 534–539\)](#) come into play here. The elite recruits its next generation from within its own circles through appointment networks, and it is wealthy enough to establish lavishly endowed research centers that have global appeal. Therefore, the academic field does not function according to the logic of economic efficiency, but according to the logic of academic distinction. And distinction has always included the privilege of the nobility, namely, to be able to display luxuries that make potential competitors green with envy.

If we consider the embedding of the academic field in the field of power (cf. [Bourdieu, 1996](#)), in which the representatives of the various fields, classes and groups struggle to shape society, we see here an extension of the oligopolistic structure of the academic field into the field of power and, via this field, into political consultation and influence on political decision-making processes. A prominent position is occupied by the US elite universities, not only in the field of power and in political consultation in the United States, but in the influence on the dissemination of scientific knowledge worldwide ([Wieczorek, 2021](#)). That a small group of extremely wealthy universities dominates the generation and implementation of scientific knowledge is the academic side of a kind of plutocracy that has emerged in the United States and shapes the development of science and the dissemination of scientific knowledge worldwide (cf. [Marginson, 2016](#)). Foundations play a leading role in this process, no longer practicing arbitrary philanthropy with their funds, but pursuing a global agenda of shaping the world, as exemplified by the Gates Foundation and its health as well as education agenda (cf. [Amarante, 2018](#); [McGoey, 2012](#)). The oligopolistic symbolic domination of knowledge and expertise by US elite universities extends far beyond the United States and applies to the entire world. International university rankings consecrate this oligopoly of knowledge generation and dissemination and cement its global symbolic domination ([Espeland and Sauder, 2007](#); [Erkkilä and Piironen, 2018](#); [Hazelkorn, 2015](#); [Kauppi, 2018](#)). Only a few universities outside the US—such as University of Oxford, University of Cambridge, University College London, ETH Zurich—still manage to claim some share of this symbolic domination. Recognition of European scientists, for example, depends on their international collaboration with colleagues from the center of global science. In this way they share somewhat in the center's symbolic capital. There is an increasing split between highly paid cosmopolitans and poorly paid locals (cf. [Kwiek, 2019](#)). Strictly speaking, a “cosmopolitan” outlook does, however, not mean “cosmopolitan” in the comprehensive sense but rather “closely linked to the center of global science.” The great mass of universities all over the world, like the mid- and lower-ranking US universities, play only a subordinate role in global knowledge production and dissemination. This constellation in the relationship between knowledge and power results in a narrowing down of knowledge, expertise, and political decision-making space. The possibilities of humankind to recognize and overcome challenges are thus restricted to a narrow spectrum of conceivable alternatives.

Oligopolistic structures of knowledge transfer

The example of the interconnectedness of pharmaceutical corporations, universities, and startups in biotechnology provides a good illustration of the oligopolistic structure of academic knowledge production and its close interconnection with business and politics. It is also an example of university-industry collaboration which transcends national borders and involves universities and corporations which operate on a transnational level so that we can speak of transnational academic capitalism ([Kauppinen, 2012, 2015](#)). A sharp controversy was triggered in 1998 by the \$25 million grant to the Department of Plant and Microbial Biology at UC Berkeley by the Swiss pharmaceutical company Novartis. In return, Novartis was allowed to send two representatives to the five-member research committee and to exploit all of the department's research findings, including those that emerge from research funded by public money such as the university's regular state budget and federal funds raised. Critics saw two problems in particular: first, the direct influence of a private company on public research, and second, the private exploitation of research funded with public money (cf. [Washburn, 2005](#); [Rudy and Coppin, 2007](#)).

The biotechnology cluster surrounding Harvard University and MIT in Cambridge/Boston, Massachusetts, is of outstanding importance in biotechnology research ([Birkinshaw et al., 2018](#); [Fochler, 2016](#); [Owen-Smith and Powell, 2004](#); [Stevens and Newman, 2019](#)). Here, there is an oligopoly structure in scientific knowledge production concentrated in a few universities directly reaching out to the world of business. This oligopoly structure is supported by a homologous oligopoly structure in the publication system. [Young et al. \(2008\)](#) demonstrate for biomedicine that the enforcement of the journal impact factor (JIF) as a quality standard for scientific publications, enforced by rankings, has created a winner take all market (cf. [Frank and Cook, 2010](#)). Only a tiny fraction of the research findings available per se are noticed and attract all attention. As with art auctions, this results in a kind of “winner's curse” for recipients. They invest so much attention and capital in processing the articles of high-impact journals that little is left for further, widely differentiated research with possibly surprising results. The knowledge value of these articles does not correspond to the high impact factor of the journals in the sense that many other publications question their results. This hinders the

progress of knowledge. Ioannidis (2005) has drawn attention to the fact that most published research findings, even those published in high impact journals, are not confirmed by further research. Publications in these journals paint a glossy picture of the research situation because their extremely high rejection rate implies that only highly significant and perfectly clean results are published. However, this does not correspond at all to the research reality which presents itself as much less clear and clean. Moreover, the oligopoly structure of the publication market has the effect of narrowing research to a few broadly investigated topics. Therefore, there is a lack of diversity of topics from which only new knowledge can emerge.

Finally, the intertwining of the oligopoly structure of academic research and publication outlets with the oligopoly of the world's leading pharmaceutical corporations means a further narrowing of the translation of research into technology. This also affects the approval of drugs for distribution in the drug market. In the United States, the Food and Drug Agency (FDA) is responsible for approving the dissemination of drugs. This is where the nexus of research, industry, bureaucracy, and politics is concentrated to ultimately distribute scientifically generated, politically desired, bureaucratically controlled, and economically profitable products on the market (cf. Carpenter, 2004; Hawthorne, 2010). The concentration of the relevant field-specific capitals among a few actors means that the tension between scientific truth-seeking, political goal setting, bureaucratic control, and economic profitability tends to be resolved in favor of economic profitability. Hearings often bring together the same experts and stakeholders who are in any case mutually committed to each other in close cooperation and form the center of power (Wieczorek, 2021). This significantly narrows the spectrum of alternative voices. The search for truth is then no longer open enough to sufficiently explore all possible risks and side effects of scientifically generated products. The consequence of the formation of oligopolies of research in the context of academic capitalism is accordingly a narrowing down of scientific and technological development.

Meso level: the superimposition of the managerial control of research on its control by peer review

At the meso level of the organization of universities, academic capitalism means that universities engaged in intensified competition for the accumulation of economic and symbolic capital rely on a strong, strategically operating management. For the purpose of best possible positioning in competition, this management internally exercises strong control over research and teaching by profiling it through research clusters and by regularly monitoring its research output and its teaching. There is a shift of power from the faculty to the administrative level. Ginsberg (2011), therefore, speaks of "the rise of the all-administrative university" (cf. Delucchi et al., 2021; Donoghue, 2008/2018; Engelen et al., 2014; McClure, 2016; Lorenz, 2012; Readings, 1996; Tuchman, 2009; Welsh, 2020). In this context, orientation to prevailing research themes, paradigms and methodological standards gains the upper hand over the free pursuit of research goals based solely on curiosity in the process of discovery, because this is the only way to avoid failure and ensure reception of one's research (cf. Hallonsten, 2021). This type of coping with competition affects middle-class universities particularly, which are struggling for recognition with scarce resources and cannot afford failure resulting from risky investments. Elite universities are much more able to invest in risky research aiming at novel findings because of their economic and symbolic wealth. At the very top, a culture of academic luxury, excellence and autonomy is celebrated while among the rank and file a culture of ubiquitous accountability and pressure to conform to established standards prevails (Gonzales et al., 2014; Mendoza et al., 2012). Elite universities can be proud of simply selecting the "best" and then let them do what they want to, the rank-and-file universities, in contrast, cannot recruit the "best" and feel more compelled to monitor in detail what their faculty is doing. They are strongly subject to the audit culture of New Public Management (cf. Power, 1997). As on the macro level, elite and non-elite universities are very differently affected by academic capitalism on the meso level.

Limited scope for creative deviance

Speaking with Goffman (1961), the monitoring tools, the visualization of every step taken in the research process, and ubiquitous accountability only allow for research autonomy in an unobserved underlife of the institution that leaves researchers the space they need to generate innovations. The latter require a high risk/high reward strategy that cannot be chosen when minimizing risk dominates research.

Studies from management and organizational research show that the possibility to deviate from organizational goals and directives by superiors promotes innovativeness and thus contributes to the competitiveness of organizations (Tenzer and Yang, 2019). This behavior is referred to as "creative deviance" (Mainemelis, 2010), i.e., the deliberate deviation from directives to pursue creative and new ideas on one's own authority. It needs free spaces in which these ideas can mature over a considerable period of time and also autonomy in allocating resources to projects. Within companies, this kind of project work requires a management that grants sufficient freedom and does not punish creative deviance, but rather encourages it, in order to address problems, for which no solutions have yet been found (Lin et al., 2016). Therefore, it is not surprising that radical innovation is listed as a positive effect of such behavior, while wasting resources and violating stakeholder trust are cited as negative effects.

For example, Lin et al. (2016) used 233 employee-management dyads to examine how managers' response to creative deviance in organizations is related to employee performance. They emphasize that employees' performance and contribution to problem solving increase if their independent creative work is recognized, whereas punishment and manipulative behavior management by supervisors hinder employees' performance. Moreover, Liu and Zhou (2020) show that research staff who feel privileged and "different" or "unique" are more likely to pursue their own creative ideas. They are also more likely to do so in the face of resistance

from superiors and other stakeholders to whom they are accountable. However, if they are granted the necessary freedom, they respond with a higher affective commitment to the organization and perform better.

As researchers are placed in multiple dependencies in the wake of New Public Management reforms, the space for creative deviance is increasingly limited. Specifically, this freedom is diminished by (1) the increasing obligation to document one's own activities, (2) by third-party funding competition and dependence on funders, (3) by monitoring through university managers, and (4) by visibility competitions expressed in rankings and citation indices. In this way, innovation is hindered because of lacking space for exploring new terrain (cf. [Anderson et al., 2014](#)).

Thus, if we apply the findings from creative deviance research to the academic field, we expect to see significant differences in the opportunity to pursue creative ideas between elite universities and the broad mass of middle and lower ranking universities. First, this is because researchers at elite universities are trusted more and are granted greater latitude for deviant behavior compared to researchers at non-elite universities, simply because of their institution's reputation. It is precisely these researchers who ensure that universities do well in rankings, accumulate scientific awards, attract external funding, and achieve high citation numbers. This in turn legitimizes the freedom that researchers has been granted. Second, elite universities dispose on the necessary resources to enable researchers to explore new terrain with uncertain outcome so that resources may be invested in vain. In contrast, researchers at non-elite universities must go the safe way to bring about visible results regularly. This can be seen both in the inverted-u-shaped relationship between resources deployed and publication output at elite universities, and in the conformity of topic choices to the mainstream of researchers at non-elite universities ([Wieczorek et al., 2017](#)). Thus, universities that dispose of sufficient resources of their own, exert less managerial control and respect researcher autonomy have a higher potential for creative deviance and for pursuing new lines of research. They allow a "high risk, high reward" strategy in the advancement of scientific knowledge (cf. [Fleck, 2013](#); [Uzzi et al., 2013](#); [Wang et al., 2017](#)).

Consolidating established lines of research and nimble knowledge production

In contrast to exploring new ground under conditions of autonomy, limited scope for deviance in research because of increased financialized managerial control in academic capitalism results in what can be called consolidation of established lines of research and nimble knowledge production (cf. [Engelen et al., 2014](#); [Hoffman, 2020](#)).

A first feature of favoring research along established lines by strong university management is the management's interest in large-scale funding through establishing interdisciplinary research clusters providing a widely visible research profile. This implies increasing size of collaborating teams. Research shows, however, that it is small teams of two to eight members, all actively engaged in research, with secure funding and little administrative work which are crucial for establishing new lines of research and achieving breakthroughs, while large-scale clusters are extending and consolidating the established lines of research ([Heinze et al., 2009](#); [Holingsworth, 2006](#); [Wu et al., 2019](#)).

A second feature of increased managerial control on research is favoring flexible adaptation to changes in funding opportunities. Research teams at sites that suffer from a permanent lack of funding or recognition by peers, or work on topics that are marginal to the respective discipline, are particularly affected by this economic logic. As [Hoffman \(2020\)](#) demonstrates in a field study on a computer science laboratory, the principals of such units adopt a strategy of "nimble knowledge production." This strategy involves (1) quickly finding provisional solutions to avoid unnecessary costs; (2) excluding complex theoretical problems in favor of "real world problems" outside of academia; and (3) quickly targeting new topics if hurdles or problems arise that run counter to the commercialization of findings. This focus may be applied by researchers out of themselves, but it may also be a result of governments intervening in the funding landscape. This strategy was observed, for example, with renewable energy research in the United States under the Trump administration, where researchers used previous findings and approaches to research to commercialize highly profitable fuels ([Jeon, 2019](#)). In such cases—emanating from researchers themselves and triggered by pressure from external actors—a purposeful ignorance of unprofitable lines of research is cultivated. In addition, there emerges ...

a fleeting attention to the long-term analytic, conceptual, and methodological problems of an academic field of research. Where this form takes hold, then, we might worry that sustained engagements with the thorniest of scientific problems can wither away as the champions of academic capitalism tell stories about how quick and clever they have become.

[Hoffman \(2020, p. 30\)](#).

Micro level: the superimposition of compliance strategies for academic survival on the curious search for progress in knowledge

At the micro level of researchers, academic capitalism translated into comprehensive monitoring of research and its achievements has the effect that researchers learn to aim at easily attainable research goals and topics to avoid failure and to get on a safe career path already in the process of their academic socialization. This calls for a conformist and adaptive habitus (cf. [Morris, 2020](#)). These are the disciplining effects of closely monitored research and teaching fueled by the omnipresence of rankings (cf. [Sauder and Espeland, 2009](#)). A difference between elite and mass is also noticeable at this level. Doctoral students at elite universities, on the one hand, have attained so much self-confidence and self-assurance, as a result of being chosen through a rigorous selection process, that they are confident to be able to break new ground in their research. They must do so if they want to have a chance of

being appointed at an elite department after having graduated. Of course, only a minority of them will make it in the end; the rest will have to make do with an appointment at a middle- or lower-ranking department. For the doctoral students at the middle- and lower-ranking departments, on the other hand, it means taking the safe path of standardized mainstream research right from the start so that their career continues on the middle-respectively lower-ranking level.

The bias against novelty

Certainly, the vast majority of about 80% of the researchers have always been engaged in mainstream research of normal science in the sense of Kuhn (1962), while it is left to about 20% to venture into new topics and methods. Even before the spread of academic capitalism, there was a “bias against novelty” in science (Wang et al., 2017), which can be explained by the academic community’s critical attitude toward uncertain knowledge not generated according to the established methodological standards. What is new about the translation of academic capitalism into comprehensive monitoring of the research process is the separation between research that is free in this respect at elite departments and controlled research in the mainstream becoming so entrenched that the broad mass of researchers at mid- and lower-ranked universities are excluded once and for all from exploring uncharted territory. This, in turn, has the effect of shrinking the potential for innovation overall, because only what sees the light of day at elite departments and only what is published in high-impact journals closely intertwined with those departments gets attention.

Incremental innovation and normal science are rewarded, and only carefully crafted articles with significant results are published in high-impact journals. This is the starting point for knowledge generation. Research on so-called sleeping beauties (van Raan, 2004) suggests that many scientific innovations are not even noticed and recognized by a broad scholarly audience. The rationale for this phenomenon is that innovative research with high novelty value is often initially published only in marginal journals, has little connectivity, and takes many years (if not decades) to be recognized (Dey et al., 2017; Yeung and Ho, 2018). To get them to awaken, they need to spark conventional follow-up research, which is more likely to be noticed the higher the rank of the journals in which the findings of this follow-up research are published and the higher the reputation of the researchers conducting follow-up research (Chai and Menon, 2019; van Raan, 2015). Scholarly awards confer greater legitimacy on both new lines of research and the scholars who help to further advance those lines of research and bring them into the scientific mainstream (Farys and Wolbring, 2021).

Looking for funding

Although autonomy and long-term funding have been variously proved to promote creativity, innovativeness, and research breakthroughs (Heinze et al., 2009, 2020; Whitley et al., 2018), nevertheless, the competition for external funding with relatively short funding periods—as a main feature of academic capitalism—has become ever-present since the 1980s. Looking for funding is everyday work of principal investigators (cf. Cantwell, 2015b). Attached to the increased competitive allocation of funds is the promise that the best scientists will be promoted, innovation will be favored, and competitive advantages of scientific locations will be generated. In fact, having to look permanently for external funding allocated through peer review according to established standards interferes with the opportunities of scholars to establish new lines of research and drive radical innovation. Greater dependence on external funding again subjects scholars at rank-and-file departments more to this effect of disciplining and normalization than their colleagues at elite departments. However, as Feyerabend (1970/1993) in particular has emphasized, the breakthrough to new knowledge requires exactly deviation from established methodological standards. This is all the easier to do the less dependent researchers are on the granting of research funds based on peer review. This may be the reason why Evans (2010, p. 444) observed more opportunities for industry-funded than government funded research to produce new insights. In contrast, as he also found, government funded research allows more penetrating exploration of issues in all their breadth and depth. Presumably, particularly distinguished researchers receive industry funding without strict peer review, so they are freer to decide on theory, methods, and subject matter than is the case with the usual publicly funded research that is subject to strict peer review. The latter, in turn, obviously appreciates methodologically standardized research within the framework of normal science and the incremental innovations achievable within this framework.

Various studies generally indicate an inverted u-shaped relationship between the degree of novelty of research and the likelihood of funding (Bourdeau et al., 2016; Gallo et al., 2016, 2018). The rationale for this finding is that the added value of the research is not recognized, but that too much proximity to previously addressed topics leads either to expert panels viewing applicants as competitors or their contribution as uninteresting. While in the former case the innovation opportunity tends to go unrecognized and the connectivity to previous research is not given, applications that are not very innovative are also not worthy of funding because they are considered trivial and not very insightful.

For example, looking at 150 research proposals in the field of biomedicine, Boudreau et al. (2016) observe that proposals with high and low novelty value are evaluated as not eligible and rejected. Project success, as measured by publication numbers, scientific impact, and societal impact, is considered as uncertain. This uncertainty, and ergo the risk of failing to meet the funding targets, leads to a lower scientific quality being attributed to the respective proposals. Gallo et al. (2016) highlight for the case of biomedicine that applicant seniority, reviewer’s expertise in a given field of research, and a priori knowledge on the applications increase the chances of a project to get funded. Additionally, they uncover a commensuration bias insofar, as reviewers overtly focus on methodological weaknesses of research proposals (cf. Lee, 2015). At the same time, there is little agreement on which applications are innovative. This is why reviews tend to be based on easily measurable rejection criteria. Furthermore, the findings of Li (2017) and

Howell (2017) suggest that an applicant's familiarity with expert panels implies a higher chance of approval. They most likely share common standards.

However, this feature of peer review is not limited to scientific bodies, but at the same time can also be observed in R&D departments in knowledge-intensive companies. Here, the study by Criscuolo et al. (2017) is instructive. Studying funding panels in an international engineering company, these authors suggest that there is not only an inverse u-shaped relationship between novelty of proposals and probability of funding (and amount of funding), but also that this curvilinear effect is amplified by the workload of expert panels. For example, reviewers who are overloaded with applications tend to be far more likely to fund projects with low novelty value than reviewers who have fewer applications to process. Thus, overcharging scholars with doing reviews—a feature of the monitoring regime of academic capitalism—works against funding research of high novelty value. At the same time, there is an interaction effect of the affiliation of reviewer and project applicant to an organizational unit. While shared affiliation has a positive effect on approval, it has negative consequences for approval of innovative projects. This may be due to the reviewers' desire to prevent innovations from within their own department that make their work look less up to date.

Taking the example of Japanese natural sciences, Wang et al. (2018) found that seniority and status effects are associated with the chance to acquire external funding and to perform innovative research. Using a combination of bibliometric analysis and standardized survey, they show that third-party funding for innovative projects is allocated to researchers who are employed at high-ranking universities, tend to be male, and already hold professorial titles. In addition, the age and networking of applicants, as measured by the number of co-authors per paper, are positively associated with funding for innovative research. Finally, Gallo et al. (2018) observe that there are large differences between reviewers and project applicants in their view of the rationale for accepting or rejecting research proposals. Based on a survey of reviewers and applicants in the life sciences, the authors find that a large proportion of reviewers attached great importance to innovativeness and risk in terms of potential failure of the project, as well as to the applicants' publication record, when evaluating projects. In contrast, only a minority of applicants reported that these three issues were addressed in the reviews. According to their reading of the reviews, there rather was criticism of the choice of methods and methodology, which is more concrete and thus easier to state than is the case with the innovative potential of research. It is simply less risky for reviewers to recommend funding based on methodological rigor than based on innovative potential.

Summarizing these findings, the peer review process in the allocation of external funding under the regime of academic capitalism rewards methodologically rigorous, extra-scientifically useful and thus at the same time "accountable" normal science. Consequently, this tends to hinder radical innovation (cf. Heinze and Münch, 2016).

The split between elite and rank-and-file habitus: self-conscious autonomy vs. anxious adaptation to the mainstream

The socialization of young scholars into the academic community represents one of the core tasks of universities (Parsons and Platt, 1973/2013, pp. 103–162). This socialization process involves both the internalization of academic values and norms as well as situationally appropriate action sets and objectives (e.g., research for the sake of research vs. research to obtain external funding). Related to this feature is the academic habitus as a set of interrelated dispositions that enable researchers to navigate the various academic contexts and situations and perform the tasks associated with the role of scholar, researcher, and teacher. Ideally, researchers are guided in this process by the academic norms of intellectual communism, universalism, disinterestedness, and organized skepticism articulated by Merton (1973 [1942]). However, the changes induced by academic capitalism do not stop at the internalization and interpretation of academic norms during the formation of an academic habitus and thus researcher personality. This concerns the formation of (1) selective ignorance of ineligible topics and, based on this, the equalization of relevant and eligible topics, (2) the increasing relevance of performance indicators, (3) the interpretation of research autonomy, and (4) the definition of research as a means to the end of gaining external funding and extra-academic attention.

Doctoral students increasingly learn during their training that it is strategically wise and a virtue to neglect research topics that do not attract government (Jeon, 2019) or industry funding (Hoffman, 2020). On the contrary, they learn that purposefully ignoring non-fashion topics is beneficial to their careers and, at the organizational level, helps sustain research units that must fund themselves primarily through external grants, and to conduct basic and applied research simultaneously (Rushforth et al., 2019). The research approaches that prevail in the competition for external funding in the context of project-based calls are associated with good research by junior scientists. As a result, competition for knowledge advancement is overshadowed by competition for external funding.

The capacity for selective ignorance and rapid redirection, coupled with the pressure to accumulate funds and permanently demonstrate one's performance, has at the same time implications for the understanding of research autonomy. The pressure to pursue research topics specified by third-party funders is particularly high among early career researchers at mid-level universities, where the perceived and formally assured autonomy of researchers is also seen as high (Wieczorek et al., 2017; Woelert et al., 2020). This is because the need to (re)align with topics specified by companies or ministries is increasingly judged to be a normal state and thus part of the belief system of the academic field. Such a normal state cannot reduce the perceived autonomy for those researchers who have already proven themselves and have internalized the competition for third-party funding (cf. Mendoza, 2007). Scholars learn how to accommodate their commitment to authenticity in doing research with the demands of being successful in the field (cf. Brunila and Valero, 2018; Cannizzo, 2018; Hall, 2018; Shields and Watermeyer, 2020).

Eventually, a most problematic effect of the omnipresent pressure to demonstrate performance measured in "international" publications is the growing market of so-called predatory publishing. Scholars in the periphery lack access to the oligopoly of respected academic publishing dominated by a small group of global publishing houses. To fulfill the expectation of publishing

in international journals they feel compelled to publish in one of the innumerable low standard journals which because of their English language are included in the duopoly of the bibliometric platforms Web of Science and Scopus in contrast to many journals publishing in languages other than English (Stöckelová and Vostal, 2017).

The counterproductive side of academic meritocracy

One could argue that the very unequal distribution of autonomy and resources strengthened by academic capitalism is most efficient, because in this case autonomy and resources are not allocated in an indiscriminate manner but according to creative and productive potential. Those scholars dispose of most freedom and resources who can make most of them, while those who cannot keep up do more modest normal science research. Following Evans (2010) as well as Wu et al. (2019), this may be a productive division of labor between research aimed at extending and consolidating established knowledge and research exploring new ground. And allocation of resources according to achievement always entails the incentive for all—the elite and the rank and file—to make every effort to improve one's performance. This argument is a kind of meritocratic theory of allocating rewards according to produced value, talent and its scarcity (Cole and Cole, 1973). In the knowledge society, knowledge growth is of highest value, it needs creative talent which is scarce, therefore, most autonomy and most resources are allocated to the most talented researchers. From a critical point of view, this meritocratic argument is blind regarding the unequal conditions under which achievement occurs and the inequality perpetuating consequences of the unequal allocation of rewards (cf. Young, 1958; McNamee and Miller, 2009; Markovits, 2019). And we can add that cemented inequality and particularly extreme inequality in disposing of autonomy, talent, and resources as in the case of a stratification of the academic field into a small group of extremely rich elite universities and the broad mass of modestly equipped rank and file universities fuels the inverted u-shaped relationship between investment and returns (Münch, 2014, pp. 223–233). Most of the rank-and-file universities possess too little autonomy, talent, and resources to contribute effectively to the renewal of scientific knowledge beyond normal science. The small group of extremely rich elite universities attracts talent and resources in such abundance that cannot all be turned into innovative knowledge growth because of excessive coordination costs, demonstration of luxury for its own sake and for securing prestige and unchallengeable competitive advantage. They build an oligopoly which is not only a source of knowledge renewal but also a device of establishing paradigms which resist attempts at change just because their protagonists occupy the most powerful positions in academies, disciplinary associations, scientific journals, and advisory committees.

Talent may arise everywhere and produce new knowledge if reasonably equipped. And it doesn't matter where new knowledge emerges, as long as it is a public good (cf. Callon, 1994). What academic capitalism is strengthening, however, is the very unequal distribution of talent and resources between universities involving brain gain for the rich ones and brain drain for the modestly and poorly equipped ones. Additionally, there is very unequal attention to knowledge production implying its concentration on the elite institutions according to the Matthew principle effective in winner take all markets (Frank and Cook, 2010; Merton, 1968). The result is limited instead of extended potential of knowledge renewal and growth.

Conclusion and outlook

Academic capitalism and market thinking have subjected higher education and research at universities to fundamental changes. The New Public Management reforms with the aim of increasing the performance of universities in research and teaching have been crucial for these changes. The corresponding changes are taking place at three levels: the macro level of the academic field, the meso level of the university as an organization, and the micro level of individual scholars. We have focused on developments that indicate counterproductive effects with respect to the improvement of education and the growth of knowledge in particular. At the macro level, oligopoly structures limit opportunities for broad-based renewal of scientific knowledge. At the meso level, increased managerial control over research and teaching, especially at the most competition-subjected mid-level universities, means an orientation toward the mainstream and a suppression of creative deviance. At the micro level, junior scholars acquire a habitus of compliance to eligible teaching and research formats, especially at mid-ranking universities. Future research should address these questions more broadly and deeply. At stake are the questions of how far academic capitalism and market thinking increase inequalities at the macro level and how far this limits the spectrum of possible renewal of scientific knowledge, how far increased managerial control of research and teaching at the meso level limits the possibilities for creative deviance, and how far academic socialization shapes the habitus of researchers and teachers at the micro level to the extent that they are capable of adapting to prevailing streams of research and teaching but do not follow the curiosity of their own accord.

Introduction

With the advent of the “knowledge economy”, higher education (HE) has increasingly been viewed as the vehicle for transformative socio-economic change. Economists Maneejuk and Yamaka conclude that while “secondary enrollment rates positively affect economic growth” it is HE which is “the key to future growth and sustainability” (2021: 520). It is no surprise therefore that research into curriculum theory has expanded as a field in the last half-century. South Africa (SA) is no exception, and HE curricula have increasingly been under pressure not only to transform the economic lives of its populace, but also to “reschool” South African society on a wide range of social issues. Examples include diversity and multiculturalism, HIV and AIDS, and internationalization, to name a few. Added to the specifics of South Africa’s realities are the pressures of globalization, a weakening economy, and an ever-increasing gap between the haves and the have nots. The result is a heady mix of demands on the higher education system which, coupled with decreasing resources, results in yet more contestation over curricula in the system.

Higher education systems across the world have had to adjust to many of the same pressures, leading to a field of scholarship on curriculum which reflects on the conceptual, ideological and pedagogical issues that arise. As Lindén, Annala and Coate argue, “[a]lthough curricula are commonly investigated in HE research the field lacks a coherent theoretical approach to explaining the meaning and the importance of curriculum, particularly as part of the special role played by HE in society” (2017: 137). The incoherence results from the continuously increasing influence exerted by external stakeholders, the proliferation of the “knowledge economy”, and the pressure for institutions to compete to prove “excellence”. These are but some of the factors influencing how curricula are conceptualized, designed and articulated.

This chapter argues for the reschooling of higher education and focuses on a reconceptualization of the role of curriculum as central to this process. It raises, critically, the need for a society-wide reorientation of universities to respond to societal needs and challenges while addressing the competing ideologies that work to shape the decisions made in the sector. Curriculum theory is used to make sense of the dynamics at stake in pivotal shifts of the contemporary movements, such as decolonization, the Fourth Industrial Revolution (4IR) and the pressure to “produce” future-fit graduates. The focus in this chapter is on the taught curricula in universities and not on the structural educational reforms that occurred, such as the introduction of qualification frameworks, quality councils, and so on. The South African context is not necessarily unique however, and there may be lessons to be learned by and from other countries, whether rich, middle-income or poor.

About curriculum

Short (1993) frames the curriculum as the disciplinary and mission-oriented or practical knowledges that are held and transmitted by the university. Practical knowledge develops in situations where human activities and behaviors “pose questions that must be answered” (Short, 1993, p. 2) before any kind of concrete or appropriate action can be taken. Disciplinary knowledges are the structures in which meta-theories of reality and knowledge are organized and articulated, and through which practical knowledge is translated from abstract to concrete, via research, teaching and observed practice. These knowledges go beyond official curriculum content to include particular sets of ethics, codes and subjective experiences that occur through program exposure (an easy example would be for example, such as in medicine and law). There are critiques of the substance of particular curricula and the particular

meanings of curriculum as a concept. Barnett (Hicks, 2018) provides perhaps the most salient of these: curriculum is a vehicle for the process of knowing and understanding, teaching content, skills and forming personhood.

Baker (1996) suggests disciplinary knowledge must be situated within the socio-historical context it emerges from and engages with. It is the socio-historical context which will inform explanatory theories that make sense of and speak back to the world. Baker (1996) points out that much of the early critical work on curriculum in the 20th century focused on the relationship between socio-historical conditions and the spheres of social and specialized knowledge (Baker, 1996). While this relationship itself has not changed, the breadth of differentiation and pace of change within and outside of institutions has created what Barnett and Coate (2005) call “supercomplexity”. In a supercomplex environment institutions are under siege and are expected to remain responsive and accountable. Hicks (2018) suggests that there is a “new kind of chaos” to the usual pressures in higher education, with greater influence exerted by external variables, and a wider array of challenges confronting universities than they traditionally have had to accommodate. Developing a comparative understanding of how curricula function and of how they are contextually located has become a crucial priority to support navigating complexity.

Barnett and Coate (2005) argue that there is a dire need for curricula to be systematically reviewed to function optimally in a supercomplex world, reshaping and disrupting spaces for learning. Without this, there is an increased risk of ad hoc decision-making and implementation, with universities caught in a never-ending game of “catch-up” in a world that changes too rapidly for existing systems to respond effectively. Definitions of curriculum vary but focus primarily on the planned dimensions of learning and not on the unintended experiences, outcomes and discourses.

Research into curriculum continues to grow as higher education faces a further paradigm shift in the meaning and nature of teaching and learning. The globalization of international markets has contributed to the rise of comparative higher education studies which treat curriculum as a phenomenon of theoretical and practical inquiry. This includes how new forms of blended learning trouble the traditional “boundaries” of the curriculum, altering the role of lecturer and student, and creating new mediators of access and knowledge through the devices and information sources that extend beyond the classroom. The intertwining of curriculum and pedagogy comes to the fore as there is a shift toward a more parochial discourse on curriculum as a driver of economic and technological professionalization. The degree to which universities are able to respond to these pressures, however, is at least in part determined or affected by their national and regional contexts, as examples from South Africa, India and Ghana show.

Defining curriculum is complex as Lindén et al. (2017) argue that the field of curriculum studies lacks a coherent theoretical approach which explains the meaning and importance of curriculum and its role. There is a tendency to treat curriculum as either the sum of its constituent elements (such as assessment strategies and modules) or as the content that gives it meaning. The authors follow Young (2013) in arguing that a “curriculum crisis” has taken hold, the solution to which has been to emphasize the importance of aspects outside of curriculum, such as national qualification frameworks, holding on to learning outcomes as essential indicators of quality and relevance, and shifting from a disciplinary focus to more practical, generalized curriculum design issues. The lack of a coherent curriculum theory has been subsumed by ideological issues, fuzzily defined in terms such as “quality”, “relevance”, “excellence” and “efficiency” (Lindén et al., 2017). What is learned and how is not treated as an instructional question with a theoretical foundation which continues to be a challenge faced in higher education systems around the world. Higher education occupies an important place in the state’s strategic planning for employment, job creation and skills specialization, and curricula too are now vital dimensions of institutional strategic planning processes and not just mechanisms of knowledge transfer (Lindén et al., 2017). The problem is that curriculum as a phenomenon is essentialized to its technical elements to render it legible for planning processes which diminishes the question of the knowledge that is at the core of what a curriculum is (Barnett and Coate, 2005). The focus shifts toward tighter policymaking and designing learning experiences toward predetermined and clearly defined outcomes. The South African experience, it can be argued, demonstrates how a focus on outcomes may detract from a more broadly conceptualized need for higher education to shape society. In simple terms, there is no cogent evidence to suggest that the shift has had the significant impact policymakers assumed it would.

De- and “re-schooling” higher education systems

The question of the knowledge underpinning university curriculum touches at the heart of the politics of knowledge, and what one defines as knowledge and the different value tags attached to it. Pathways to epistemological and epistemic access have become a major curriculum turning point in the last decade in South Africa. Universities have been challenged continually to address the exclusions and silences within canons of knowledge that continue to act against deep social change (Sayed et al., 2019). In assessing the history of education in the South from colonial times through to the post-apartheid era, Soudien defines what he sees as the fundamental driver of curriculum in the apartheid state: “social difference, as opposed to, say, pedagogical reform” (2010: 20). His work demonstrates that curriculum development processes in former colonial countries required “a forceful incorporation into the dominant ideological structures of the world” (Soudien, 2010: 20). In South Africa, this social difference was encapsulated in the system of race, which was not critically interrogated after 1994 and as a result continued to act as a “definitional boundary” in the “new” South Africa (Soudien, 2010: 43): “The point to note in this analysis is how comprehensively the new curriculum has catalyzed and even amplified the major vectors of discrimination inherited from the past”.

The concepts of de-schooling and re-schooling are useful for making sense of the contradictory processes effected at the turn to democracy. “De-schooling”, as coined by Illich (1970), is a critique of schools as institutions that are ineffective learning sites which alienate and dehumanize learners and the process of learning. Illich’s work called for more open-ended, networked and holistic sites

where learning could take place, such as libraries and museums. The focus on “outcomes-based education” shares this appeal in its emphasis on unique and learner-centered experiences. However, there is also a conservative application of de-schooling as a framework which seeks to question the public value of education as a whole, shifting focus to whether schooling delivers on private outcomes such as higher salaries and greater social mobility, and disaggregating certifications to technical competencies (Sukarieh and Tannock, 2019).

Re-schooling is defined by Hartley (1997) as the *reinvention* of schools or education systems toward visions, purposes and practices that are reflective of and responsive to changing social conditions. The dual focus on decolonization and the 4IR represents one example of how re-schooling efforts are being made in higher education in South Africa currently. This chapter develops a working definition of re-schooling as changing the ways in which policy seeks to address core issues which are educational *as a result* rather than as a cause—in this case, society-level issues or challenges that cannot be resolved only at the level of curriculum. This also requires addressing the temporal challenge in curriculum design, which Soudien defines as the crafting of higher education policy for the society that the post-apartheid South African state *wanted* rather than the society it *had* (Soudien, 2010). This vision-setting approach belied the cleavages and inequities that the system inherited, deepening existing inequalities over time. The discourses of decolonization and 4IR are also somewhat competing visions for the system, but it is essential to understand both in order to make sense of the demands of reschooling society for more socially just and responsive higher education.

The challenge that emerges is how to synthesize a range of normative ideals and priorities—from sustainable development to nation-building, decolonization and the 4IR—in ways that produce cogent learning experiences within the broad scope of the disciplines in the university. That all of this must occur within the existing curriculum policy architecture in South Africa means that institutions will approach these priorities differently based on their own situational dynamics, constantly renegotiating the balance between policy and how this is implemented. The challenges to curriculum development that have most impacted higher education in the post-1994 period have been *#RhodesMustFall* and the articulation of the Fourth Industrial Revolution (4IR) as a critical epoch in global development. The encapsulation of the rejection of ostensible transformation saw the *#RhodesMustFall* student protests spread across South Africa and internationally. Student activists highlighted the lack of transformation of universities, and their resulting alienation from both the institutions in which they studied, and the epistemologies to which they were denied access. More recently, COVID-19 provided fertile testing ground for how South African higher education institutions have developed to address the complexities of the 21st century, notwithstanding the complex social and economic strictures within which they work.

The politicization of curriculum

The politicization of curriculum is not unique to any country, especially as decision-making around canons of knowledge remains inherently political. Its particular form in South Africa as well as other examples from India, Kyrgyzstan, and Ghana are instructive. Recently, the University of Delhi became a site of struggle over curriculum in four disciplines. English, Political Science, History and Sociology have fallen foul of the Indian government’s need to control universities at the cost of the academic freedom. Khattar (2019) shows how the Hindu nationalist party, *Bharatiya Janata* (BJP), is attempting to establish a Hindu majoritarian state by subverting the existence and histories of cultural, religious, and political minorities. The conflict is clearly politically motivated and demands relating to curriculum align directly to the interests of the ruling party. The University of Delhi has rebutted these requests, nonetheless the national conflict affected elections for students’ and staff’s representative bodies. This is an unambiguous example of the manipulation of curriculum by political powers.

Broadly speaking in the African context, Tade Akin Aina notes “the recognition that Africa’s stories of the development process are narratives of blocked transitions, routes not taken, itineraries hijacked, highways populated by robbers and bandits, and journeys led by shifty and unreliable scouts and guides (2010: 22). Against this backdrop, he argues, the “terrain of African higher education continues to resemble a thick forest of institutions, systems, and practices lacking clear and distinct tracks, values, and goals, or a mission and vision that connect the institutions and systems sufficiently to the major challenges of their contexts (whether global or local)” (2010: 23). Despite this, African universities remain important role players in the economic and social constitution of society, albeit constrained by the “blueprints” of institutions used to accredit universities by regulatory bodies (2010: 36). These institutions will need drastically to change their approaches to knowledge production and to the partnerships they select if they are to become “equal players in the global arena while remaining relevant nationally and locally” (2001: 36).

Shadymanova and Amsler (2018) offer a fascinating account of the Kyrgyzstan education system post the collapse of the USSR. Higher education institutions, despite being subject to government regulation, market forces, “new legal and political frameworks, changes in the relationship between higher education and labor”, nonetheless expressed their own institutional “strategies and responses to environmental changes” (2018: 230). One year post independence from the USSR, the Kyrgyzstan government enacted a law “On Education” which sought to reform the system for the political and economic context. Significantly, the law seeks to develop diverse educational programmes, “new learning forms and technologies”, and new funding sources (2018: 236). The state retained responsibility for basic funding, for standard setting for the different levels, for the approval of priorities in curriculum development, among other aspects. HEIs in Kyrgyzstan are required to adhere formally to quality assurance requirements and must meet the requirements of the state to operate (2018: 236), resulting in a significant increase in student numbers across the system.

In a less overt example, Gyamera and Burke (2017: 14) argue that transformation in Ghanaian universities has been perceived of in terms of “Western-oriented standards and neoliberal discourses, where there is a privileging of the economic”. The authors

comment on the failure to consider questions about the interplay between curriculum, knowledge, and power. As in South Africa, there can be no reliance on a “common sense” approach given the implications of this, and its historic marginalizing of local and indigenous knowledge forms.

The apartheid legacy of defining and dividing institution types by race or jurisdiction wrought permanent damage on the foundations of South Africa’s educational landscape. The political turbulence of the early 1990s with its emphasis on restructuring South African society along equitable lines saw the introduction of swathes of legislation designed to effect fundamental social and political change (for example, the *Employment Equity Act*, passed in 1998; the *Labor Relations Act*, passed in 1995; and the interim and final constitutions, passed in 1993 and 1996 respectively). With the transition to democracy in 1994, and against this highly iniquitous historical backdrop, the new state looked to the hotly contested HE arena as a critical lever for social, political and, significantly and as in the Ghanaian context, economic change. Opening access to higher education to all, regardless of race or other grounds would, it was argued, set the foundations for addressing apartheid’s negative structural and social legacy. The simplicity of the connection between increased access to education and employability and the resulting economic (and social) transformation was, however, thoroughly under-interrogated.

The complexities of such assumptions for higher education are replete. In addition to the demands of social context, the purpose of a qualification, its location in a discipline, the teaching and learning culture of an institution and the interplay between institutional, national and global contextual forces, universities were and are seen as responsible for articulating this change at the level of the learning program. At the level of the program of learning, and what takes place in a university, is the module, which is in the hands of the individual lecturer, or group of lecturers. Applying the imperatives to “curriculum” is thus almost intangible, and impervious to measurement. In addition, and as an added complexity, it is only recently that universities have begun to think about the pedagogies underpinning curricula. As universities change, and regardless of what these changes are, they translate these re-defined purposes and actions into their society. They feed into and from the challenges and complexities they are surrounded by and are required somehow to wrestle these into their curriculum planning processes (Barnett and Coate, 2004; Cross and Atinde, 2015).

Ramrathan argues that, despite the degree and extent of change in the SA HE system, “fundamental curriculum transformation has not yet taken place” (2016: 2). Using the Bachelor of Education as an example, he argues that the lack of transformation is because “what is kept and what is left out [of the curriculum is] based on what political decisions govern their actions” and programmes that did meet the demands of the Department of Higher Education were not approved for offering (2016: 7). Deep transformation of the curriculum, he argues, will be effected by obtaining new insights into curriculum, by focusing on “situated and propositional ontologies, innovative and transformative ways of inquiry” and by “embracing complexities and uncertainties” (2016: 7).

The paradox lies in that the architecture of a curriculum depends on decisions being made about how teaching and learning will take place. Lecturers use the content of their disciplines to create and teach the knowledges necessary to “graduate” the student with a set of intellectual and practical assets recognized as a qualification. But, as Bernstein (1996, p. 47) points out, it is through curriculum that society “selects, classifies, distributes transmits and evaluates” what it considers “to be public, [which] reflects both the distribution of power and the principles of social control”. This means that curricula are complex compositions of value-judgments intended to translate into social and individual value through graduates. The question of what is to be valued, and how it is to be articulated, remains a contested issue between different stakeholders in the higher education terrain, with reschooling offered as one process through which this question may be resolved.

Clearly, and as discussed elsewhere in this chapter, there is no uniformity in defining curricula, and it is also not easy to measure. Even from a policy perspective, there is no shared definition of what it is that the various imperatives should impact on. Using the state’s own definitions, it is the university’s responsibility to give effect to the policy directives through learning programmes and qualifications. The nature, form and translation of change occurs in a particular learning space beyond the reach of a bureaucracy to find. If the past decade in South African higher education taught universities anything, it is that what universities thought about themselves and what students thought about them were leagues apart, and it remains unclear whether it will be curricula alone that bridge that gap. Re-schooling offers an opportunity to orient interlocking systems and mechanisms of social reproduction toward more robustly determined developmental and ethical goals. The next section considers this in light of the continued prevalence of outcomes-based thinking in South African higher education.

A critique of the outcomes-based approach in SA education

There is widespread critique of outcomes-based education (OBE) in SA which, although having been withdrawn for use in schools, remains the model for higher education. As in Australia, SA regulators adopted OBE given its links to constructivist approaches to learning, focusing on the uniqueness of the learning experience for different students (which acquires more emphatic meaning given South Africa’s history), and the need to relate learning to “real-world” experiences. However, as Donnelly points out, a flaw in constructivism “is that it takes a common-sense observation, that learning is actively constructed, and that each person internalizes learning in a unique way and distorts it to such an extent that it becomes counter-productive” (2007: 12). Jansen (1998: 321) identifies other weaknesses, posing the following questions:

Do outcomes in fact deliver what they claim? How do outcomes play out in a resource-poor context? Can outcomes survive their psychological roots in behaviourism? Do outcomes in different contexts mean the same thing, e.g., are outcomes specified for education equivalent to those identified for training?

Having progressed through an OBE-driven system, and as a result of a lack of clarity on what the learning outcomes are or should be, coupled with a failure to assess these, students end up with “pseudo-knowledge, pseudo-skills, pseudo-attitudes and pseudo-values” (Malan, 2000: 22). According to Spreen and Vally (2010) the challenges SA faced post-apartheid led to the implementation of OBE as a means of differentiating the “new” SA from the old. In the new South Africa, it was anticipated that the “skills, knowledge and values [needed] for social justice, equality and development” could be provided through higher education (Spreen and Vally, 2010: 40). Critical to the regulators also (Sayed et al., 2019) was the perceived link between economic development and OBE. Problematically, however, education alone could not address the “social inequalities that were the legacy of apartheid education” and OBE “mostly failed and, in fact, resulted in exacerbating rather than overcoming inequality” (Spreen and Vally, 2010: 40). It is possible that the transformative and educational burden placed on OBE was simply too much. It is clear that in practice it did not work, although this is certainly more tangibly defined in the schooling sector and more intangible in higher education.

Most critiques of OBE have focused on school education, and it is fair to argue that OBE has, in large part, simply been ignored by the higher education sector, aside from where it matters: in engagements with the regulatory bodies. As the events of 2015 highlighted, universities had largely continued as they always have, with decisions regarding modules and curricula remaining in the domain of the individual lecturer. The OBE clothing simply enrobed the same body higher education had always had. In addition, neither OBE nor other systemic interventions in higher education have been able to resolve the socio-political, economic and other woes that bedevil SA society. This has meant that the re-schooling of both basic and higher education that was expected to occur through post-apartheid policymaking has largely failed through a failure to address the root causes of continued educational inequalities.

These root causes were sharply defined by the #RhodesMustFall student movement beginning in 2015. Students protested against untransformed university curricula, institutional cultures and teaching practices, as well as the material barriers to participation for poor students which included the high cost of fees. They issued a call for the decolonization of higher education including the removal of barriers to access to an important lever of social mobility in a society still grappling with the inequities of its apartheid past. While in the aftermath, universities have engaged with these concerns at both the curriculum and material levels, the need to fundamentally re-school society was placed on the backburner—despite students’ demands indicating that this would be essential to realizing the goal of decolonized higher education (Jansen, 2019).

Strategic levers and curriculum

There is no question that the history of education, and not only HE in SA, is brimming with rhetoric. Currently, the policy rhetoric is that curriculum change in HE takes place according to a set of “strategic levers”. By way of illustration, since 1994 higher education has had overtly to respond, as a matter of national policy, to a multiplicity of imperatives, often ill-defined and vague, with few attempts to arrive at a shared understanding of their meanings. The notion of “transformation” for example, remains largely undefined so that despite having “transformed” their staffing and student demographic profiles, for example, numerous universities across the country faced the accusation of not having transformed their curricula, as the events of 2015 and #RhodesMustFall so clearly indicated.

Other policy imperatives since 1994 have included HIV-AIDS “awareness”, entrepreneurship, employability, equity and access, and student success. These are stacked on top of the introduction of the National Qualifications Framework (NQF) (designed to facilitate articulation across the sector), OBE discussed above, a variety of transformation reports (for example, RSA, 2008), the realignment of qualifications to meet the National Plan and a new framework for higher education, the 2015–2016 discourses of decolonization, the post-2019 discourse of the 4IR, Sustainable Development Goals, and the current focus on the “21st century graduate”. The result is that all of these imperatives have been supposed to play out in the hotly contested space of what is termed curriculum. What is not in question is the enormous pressure exerted on academic curricula to comply. It is also not clear to what extent the meanings of these imperatives or levers are shared across 26 public universities, the private higher education sector, thousands of academics, tens of thousands of qualifications, and countless curricula, as misnomers and misimpressions result.

It is not within the scope of this chapter to state with any degree of certainty whether these “imperatives”—or which of them—has resulted in deep, meaningful curriculum change across the sector. Even where change can be said to take place, it cannot be argued that this has occurred with any evenness across or even within institutions. At the level of curriculum, a simple example is that the insertion of a module on African thought into a qualification does not mean that “decolonization” has occurred. The same is true for entrepreneurship, as Nabi et al. (2018) demonstrate: entrepreneurship education can “foster but also decrease entrepreneurial intentions”. Where increased, students have a “theoretical understanding of the start-up process ... combined with a strong inspiration”; where it decreases, however, “students are developed as individuals” but have a “more realistic and practical perspective on entrepreneurship” (Nabi et al., 2018: 463). As a consequence, aspects of curricula amendments—whether to programmes, modules or the content, may tend to become mere ciphers or symbols of the change they are meant to achieve. There is, equally, no measure at present to determine whether change has taken place or, if it has, that it has been in the particular direction envisaged.

Part of the difficulty is the nature of measurement and what would be measured even if there were such a measuring tool. As a result, assessments of the impact have tended to remain anecdotal at best.

Supercomplexity as a driver of curriculum change

The above pressures on higher education may be seen as discrete, but as the SA context demonstrates, this is not the case. This is simply an example of how supercomplexity impacts curriculum decision-making in a single higher education system (Barnett and Coate, 2005). There are the additional contextual and regional pressures pertaining to the global South, especially as it seeks its own solutions distinct from those proffered by the global North. Added to this, the (super)complexities impacting on curricula are quite literally the lived realities of the majority of South Africa’s students—whether climate change, poverty and economic austerity, or globalization, to name a few. In this way, the politics of knowledge continues to frame the robust question of what is to be learned, which within the contested arena of SA higher education remains no simple feat. This includes the making of curriculum choices that are specifically extraverted in nature, geared as they are toward producing graduates for a global marketplace (Tyler in Lindén et al., 2017). From the student perspective, there is pressure to be “job-ready” and be able to find or create employment and having the skills to do so. In this way, issues such as unemployment form part of the sphere of influences that drive changes to the curriculum through both state policy and ground-level pressures. The official South African unemployment rate of 32.5% is concerning, with the youth unemployment rate for ages 15–24 years and 25–34 years at 63.2% and 41.2%, respectively (Stats SA, 2021). Given the complexity of the South African contexts of higher education, the increasing pressures on curriculum are not likely to ease, and yet a better approach is clearly needed.

Employability continues to be a central issue of curriculum development in many African universities (Gyamera and Burke, 2017). Gyamera and Burke (2017) argue that the desire for “world-class”, “excellent” universities, defined in terms of the higher education systems of wealthy Northern countries, exerts significant influence on decision-making in curriculum planning in order to streamline graduates into an international labor market and knowledge economy. University leaders in their research spoke directly to making curriculum decisions that foregrounded expertise or experiences in the global North as a means of attracting funding or partnerships, or being pressured to do so in order to access donor finance (Gyamera and Burke, 2017), with the result that curricula are being amended on an often ad hoc basis to take on new perspectives and theories of change, while at the same time being standardized into the image of global curriculum planning that may be at odds with the contextual needs of students and staff. This results in, for example, the rationalization of micro-economics and other “orthodox” branches of Economics at a Ghanaian university in favor of courses that offer more practical and “competitive” skills—representing a break with critical forms of disciplinary knowledge that inform research and other high-prestige activities in the global North.

In addition, universities have to account for a myriad of considerations from stakeholders in addition to government and civil society, and which include labor, business and market institutions. The focus in South Africa on entrepreneurship and employment—to address the aims of development and redress—is a normative position that further shapes the tendency toward demonstrable and accessible “packages” of learning outcomes, as indicated in the linkages to OBE above. The competing pressure for the curriculum to factor in issues such as globalization, interdisciplinarity and preparation for 21st century conditions is also evident. This introduces key attributes such as lifelong learning, critical thinking skills and social responsibility which also require adaptation and orientation into competencies that can be defined and measured effectively.

Universities are also required to provide learning opportunities for students to become data and media-literate in a world of changing representations. This means offering students the knowledge and social relations needed to enable them to critically read—not only cultural texts and how these are regulated by various discursive codes—but also how such texts express and represent different ideological interests (Giroux, 1992:135). The complex array of skills and attributes curricula are meant to address places pressures on lecturers and students alike who are required to translate this ever-changing scope into meaningful, practical, intellectual and personal skills and competencies despite learning gaps deriving from specific lived realities. Some of these skills, attributes and competencies acquire a political flavor when understood in the context of macro-political events and trends, as the section below describes.

Meeting the needs of decolonization

The current focus on cultivating standardized and transferable experiences is counterintuitive in the context of renewed calls for the decolonization of HE. The term “epistemological access” is regularly used in South Africa to explain the extent to which students’ prior knowledge and experiences are recognized and incorporated into higher education. In South Africa, this produced a reckoning with the reality that many of the curricula in universities continued to be informed by colonial epistemologies even after the transition to democracy (Le Grange, 2016) which drove the curriculum debates during the 2015 #RhodesMustFall movement and after. Masenya (2021) writes that the issues raised by students gave rise to the interrogation of curriculum decision-making and learning content, and the relationship between the two. At the forefront of the debates that raged was the deliberate and sometimes unconscious exclusion of epistemologies associated with black contemporary and indigenous thought, as well as literature and critique by black scholars.

The decolonization movement in South Africa also touched on the material experiences of students and the question of the relevance of their studies, specifically in the context of a difficult job market and high expectations of returns to higher education. Gya-mera and Burke’s (2017) findings in relation to the Ghanaian case are instructive in this regard. There is a continuous challenge in balancing relevance to labor market outcomes with the need for a curriculum orientation grounded in Africa, drawing on its knowledge systems and responsive to the needs of states located in the global South.

The 4IR and planning for the 21st century

The 4IR signals a further shift in the imperatives underpinning curriculum in South Africa, as well as the linkages between curriculum and social or economic outcomes. Explicit decisions to include 4IR in agenda-setting for curriculum policy has given rise to the inclusion of new sets of key competencies, skills and capacities, as well as the personal attributes required by 4IR-ready graduates. The 4IR is characterized by the expansion and integration of exponential technologies and the reliance on knowledge and big datasets to inform computing, analytics and real-time decision-making (Schwab, 2016). On one hand, it brings into focus the growing influence of artificial intelligence, machine learning and the Internet of Things on changes to the nature of work and the economy. However, it also heralds a new understanding of how technology and data are shaping the everyday experiences of human life. Literature on the 4IR and the incorporation of the 4IR into education policy generally begins from the standpoint that what universities are currently producing in graduates is ineffective and insufficient for the current technological and social shifts underway (Menon and Castrillon, 2019).

The greater challenge at work in the implementation of the 4IR in the curriculum has to do with the fundamental axial shift implied by the transition to a new set of conceptual and practical tools—what Bruno-Jofré and Zaldivar (2012) call the shift from the page to the screen. Within this new technological normativity, there is a rupture implied where the notion of self is reconstructed, alongside consciousness, social relations and relationship to the world (including the environment). This occurs both through the content and substance of what is to be learned under this new paradigm, as well as the technologies and tools to be used to facilitate learning.

The future of work will demand graduates that are able to engage critically at the interface of technology and society, having developed the specialized disciplinary knowledge and skills to translate the conditions of the future in the contexts where they find themselves. This should not occur in a vacuum from other questions such as what it means to be a graduate of and in Africa, and with an African identity. The tendency to focus on the 4IR at the level of technological penetration has yet to grapple with the social change processes that this shift will catalyze, or the contemporary forces that continue to shape existing imperatives in curriculum formulation. Universities are still required to determine priorities within a contextually grounded position that emerges from their location along specific social, geographical and political axes. It is therefore possible to bring the social and technological shifts promised by the 4IR into dialogue with coterminous visions for higher education, including decolonization and social responsibility.

It is important to underscore the positioning of humanity and the physical world at the core of how digital technologies are to be integrated into society. The question of what knowledge is to be valued in the curriculum unearths a second question—that of which vessel, human or machine, will that knowledge be processed, filtered and transferred by and to what end. Ensuring that this industrial revolution harnesses the creative benefits of new technologies in support of a renewed social vision also holds the potential to unlock disciplinary knowledge from its silos, focusing instead on broad social questions and the coordination of different knowledges and sets of skills toward addressing them.

The question of how to deal with the politics of knowledge is universal. What is defined as knowledge and the value attached to the knowledge is related to questions of power and to structural and other constraints. In the words of Paolo Freire, “The starting point for organizing the program content of education or political action must be the *present, existential, concrete* situation, reflecting the aspirations of the people” (2005: 95, emphasis added) without which there is the risk of “preaching in the desert” (2005: 96). Soudien’s evaluation of the history of education in South Africa from colonial times through to the post-apartheid era echoes Freire’s words. Through a detailed historiography, Soudien argues that social difference in the region always “congeals around race” (2011: 35) which has significant ramifications for South African education which remains as the definitional boundary of post-Apartheid South Africa.

Despite the change of government in SA, at the core, the neo/liberal view of the human remains: as a rational, “conscious and deliberative individual whose subjectivity is derived from his or her engagement with the world of meaning in a fully responsible way”. What such a conception fails to address, however as Soudien points out is “the extent to which subjectivity in South Africa is a raced, cultured, gendered, and classed experience” (2010:41). It is a moot point that South Africans’ lived experiences remain racially, geographically and class bound. Policy does not, however appear to acknowledge this in its sublimation of the liberal view of the person and, as a result, fails to “engage with the sociological reality of the everyday” (Soudien, 2010: 41). In this way, rather than transforming society, there has in fact been a deepening of these inherited differentiators. In Soudien’s view, education policy acted as though the South African landscape “was already the society they wanted it to be, a largely middle-class one” (2010: 43). As a result, policymakers did and do not accurately understand the “subjects its curriculum is talking to” and so “[r]ace sits almost tangibly on the post-Apartheid landscape” (2010: 44).

Higher education forms part of the critical dimensions of Sustainable Development Goal (SDG) 4: inclusive and equitable quality education and lifelong learning opportunities for all. Higher education also forms part of the strategies designed to meet

a number of other SDGs, such as those relating to poverty, health, scientific innovation and economic growth (Kioupi and Voulvouli, 2020). While this highlights the important status of higher education in contributing to and shaping changes in society, it represents equally a new pressure exerted on curricula to engage with and articulate sustainability in ways that can be measured to satisfy reporting on SDG progress. The challenge that emerges is how exactly to synthesize and articulate this range of normative ideals and priorities—from sustainable development to nation-building, decolonization and the 4IR—in ways that produce cogent learning experiences within the broad scope of disciplines in the university. That all of this must occur within the existing curriculum policy architecture in SA means that institutions will approach these priorities differently based on their own situational dynamics, having constantly to renegotiate the balance between policy and how it is implemented.

Fundamentally, and as the South African, Ghanaian and Indian examples so aptly illustrate, however, is how curricula and the underlying power and other contextual issues remain unchallenged. Problematically, “discussions about the transformation of higher education after 1994 did not include any significant deliberations about the curriculum and Eurocentric hegemony” (Heleta, 2018: 54). Universities were consequently able to continue as is, until the 2015 #Feesmustfall movement which raised valid issues of equity of access and affordability of higher education. #RhodesMUstFall focused on the slowness of transformation in the SA higher education system including curricula, teaching and learning as well as the lived experiences on campuses. Writing on the US, Macedo refers to the failure to interrogate race, ethics and ideology “the foundation for ... the pedagogy of big lies” (in Heleta, 2018: 55).

There is no question that the continued and relentless pressure on curriculum as the vehicle for change places universities in the invidious position of trying constantly to achieve diverse, often national and institutional imperatives, while at the same time presenting a clear and coherent take on what its “core business” actually entails (Swartz et al., 2019: 568). What is clear is that universities have now, as part of their “core business”, come to adopt a role in addressing inequalities not only in relation to curriculum, but more directly in terms of social and economic inequality, seeking actively to improve the position of students while also enabling “contextually grounded teaching and knowledge production” (Swartz et al., 2019: 578). To go further than this would be to use universities in the reschooling of society, re-locating them as vital social centers through which communities are able to participate in engagements, processes and activities that share the knowledge and innovation created in these institutions. This would not only revitalize the sector, drawing it closer to contextual issues and demands; it would also ensure the full use and reach of universities’ resources. In school contexts in New Zealand, Brown (2020) finds that this can include use of campus meeting and learning spaces, on-site medical facilities, technology and art/design centers. Issues of access in higher education have foregrounded the student experience without acknowledging that universities are contextually embedded institutions that can serve important social functions. Recreating the “ivory tower” into a social resource is one avenue through which this can be achieved.

Conclusion

Curricula must be anchored in reality. For a curriculum to take effect, it must have the requisite clarity and consistency of a sound disciplinary, theoretical or vocational background needed to ensure appropriate academic activity (Winberg and Winberg, 2017). Curricula must be determined by context and pedagogical approaches. The changes needed are multi-layered and require more than top-down policy statements about the imperatives or levers for change faced by the body politic. In addition, speaking through curricula to the contexts of the students means that explicit attention to being an African graduate and to having a Pan-African identity or responsibility is essential. The global challenges encapsulated in the SDGs are arguably key to ensuring graduates able to thrive in these contexts. Clearly some professional orientations lend themselves more readily to this than others, but a requirement of curriculum must surely build the future graduates’ ability to recognize and address their contexts.

If a university is committed to a conscious process of transformation as a result of which students will be prepared for contemporary, supercomplex (Barnett and Coate, 2005) contexts, such change can happen only at the level at which curricula decision-making takes place. This is a crucial point—curricula must not only be cognizant of the students, but about where decisions about curriculum are made and by whom. Curriculum cannot be determined at the level of national policy nor even in most cases at institutional policy-level. As Luckett and Shay have argued, the “expansion of the HE system itself has not led to equity—and we would add—nor is it possible for an HE system to achieve this in isolation from radical transformation of the national and global economic systems that structure it” (2020: 3).

Teaching and learning is not divorced from the social location of a university, its students and faculty. As universities transform and evolve, new societal purposes, functions, challenges, complexities and pressures arise to be grappled with in curriculum planning (Barnett and Coate, 2004; Cross and Atinde, 2015). Reschooling HE in SA is a supercomplex phenomenon, with consensus that curricula are the battlefield in a perpetual site of struggle.

Introduction

Education pathways into and within higher education are still more or less straightforward, by and large: young adults graduating from upper secondary education enroll mainly directly into university, which they leave with a bachelor or master's degree. Depending on the country and its educational tradition, they may enter the employment system with the bachelor's degree and return later or they continue directly to the master program. While university education is the most important pathway into employment in various countries, many countries have a vocational education and training (VET) system, which offers similar life and employment chances than the university education. However, in many countries VET is not yet reality, particularly not in relation to high-qualified jobs. And the attractiveness of VET depends to some extent on the opportunity to move on the university education.

Following these pathways, initial education ends commonly at the early to mid-twenties either with a university degree or a vocational qualification. While further or adult education plays some role already around the globe, it is likely that it will play an even stronger/more important role in the future. Moreover, the profession or occupation learnt during initial education may no longer serve as foundational core area for future pathways when moving up the career ladder to the extent it did in the past. Instead, people may learn different professions or occupations and shift from one to another and/or progress horizontally and/or vertically.¹

While traditional pathways remain important and relevant for large parts of the cohort, the share of individuals following a more flexible pathway is increasing. On the one hand, this concerns those entering the first or second stage of university education, following vocational qualifications and/or parental leave or a lower university qualification. On the other hand, the university system provides additional qualifications, such as, for example, MBAs, which are not necessarily formally recognized within the National Qualification Framework, but by the economy and employers. Vocational streams also offer advanced qualifications, such as, for example, master craftsmen, etc. Eventually, professional specialisations play another key role for those who plan to advance their career in one way or another.

Cultural and traditional structures play a key role in this respect, while the university system is more or less the only route to follow for those with higher educational aspirations in the vast majority of countries, other countries provide different options with more or less comparable employment opportunities. The German speaking countries, Germany (DE), Austria (AT) and Switzerland (CH), for example, are well established and recognized examples for the later. Yet, it should not be overlooked that the dual apprenticeship training system has a history of almost a millennium (Bank et al., 2015).

Finally, the education system itself is changing strongly: While education policy is focusing the formal education sector, e.g. school or university education, new media, such as, for example, LinkedIn and YouTube are becoming part of the learning ecosystem. This same applies to other EdTech companies, whose ties are more or less closely tight to the core education system (see for example: Rivas, 2021). As for many other sectors, the education sector has started – and will proceed – to re-invent itself in the light of ongoing developments: key drivers for future directions are the digital and green transformation which have started to change the economy, the society as well as our private lives already a lot over the last decades, and will continue to do so over the coming decades (Langthaler et al., 2021; UNESCO, 2020, 2018, 2017). Digitalization and automation – as well as climate change, sustainability and green skills – are about to redesign the world of work, its business models and – correspondingly – jobs as bundles of tasks as well as tasks (World Economic Forum, 2016). While early studies on the impact of digitalization on jobs suggested that many jobs will disappear, more recent research indicates that – while still large numbers of jobs will disappear – even

¹Vertical progression means, for example, to enter into higher education after graduation from VET or from (initial) VET to more advanced VET (e.g. master craftsman), while horizontal progression means to enter into another qualification at the same level, e.g. from one VET qualification into another VET qualification or from one BA-programme to another.

more will arise newly, with the major impact of jobs changing in the light of digitalization and/or green skills (e.g. [Cinco, 2021](#); [Orr et al., 2019](#); [Effenberger et al., 2019](#); [Frey and Osborne, 2017, 2013](#)).

Another driver of new pathways of learning is the prolongation of lifetime, which will possibly go hand in hand with an extension of working lifetime: if people will even more frequently turn 90 or even 100 years of age, they may also be supposed to work till they are 70, 75 or even 80 years of age. This would mean that people are working for more than 50 years, maybe even more than 60 years, if starting early to work after leaving school with a lower secondary qualification.

Digitalization does not only change the way we live and work, but also how – and what – we learn as well as the competences needed. It has become even more common to use the internet for any form of learning, particularly in times of the COVID-pandemic, when schools and universities were closed for some time and courses and classes were delivered only at a distance (see for example: [Munoz-Najar et al., 2022](#)). In addition, youtube and other comparable programmes are a natural way to learn (even during leisure time), particularly for young people. In recent years, it has become much easier to live, for example, in Germany and enroll in a study program or a course module at an US university – without moving to the US. Eventually, various platforms, such as LinkedIn etc., act as learning providers and offer content for premium clients. These new forms of learning do not replace the more traditional forms of presence learning in the classroom but complement it ([Costa et al., 2021](#); [Head et al., 2015](#)).

These different factors suggest that the education systems will have to reinvent themselves and complement the traditional structures and learning opportunities, with new forms of learning as well as with opportunities for new learning pathways, incl. more flexible options.

This view on changing learning and education pathways complements the common view on the implications of digitalization on learning, which is focused a lot on technology, infrastructure as well as on learning itself, incl. the opportunities of artificial intelligence.

Future learning pathways

Adding up the present situation, the share of people gaining higher qualifications is growing, time span in (initial) education is much longer than in the past, and the share of adults engaged in learning activities after initial education is growing. Depending on the definition of adult learning, up to 100% of adults are engaged in different types of learning. Yet, different from primary to tertiary education, adult learning is not necessarily focused on (formal) qualifications and certificates, though this also depends on the education system, its set-up and, particularly, its tradition ([Ramirez, 2018](#); [CEDEFOP, 2015](#)).

The trends briefly mentioned at the beginning of the article demand not only higher – or more – skills and competences, but also to keep aligned with quickly changing ongoing developments as well as to update or refresh skills and competences more frequently. In addition, employers may be less focused on formal qualifications, particularly in high-in-demand professions. Each single aspect and even more the combination is likely to lead to a diversification of learning pathways, which is also driven by the role of digitalization in education – and particularly in higher education.

The following models aim to symbolize the different options for the future in a simplified way²:

Model 1—Tamagotchi: higher education for a good start in employment life

Tamagotchi describes a learning model that is focused on the traditional learning path, where learning takes mainly place at the beginning of life (till the early or mid-20s), with limited learning later in live. In this model, knowledge and competences are at a high risk to become outdated, sooner or later. Alike many other goods, knowledge and competences are deteriorating and are to be depreciated. As for the Tamagotchi which “died” if not fed any longer and enough.

In this model, *students* are at the beginning of their careers and university education takes place immediately after graduation from upper secondary education. Students study full-time until the end of the study program after three or five years, depending on whether they are aiming for a Bachelor or Master degree and study as foreseen in the curricula. The purpose of the higher education studies is to acquire a formal university degree and to create a knowledge base that enables a successful transition into employment. Once the graduate left university, short programmes and courses are the models of further learning, usually non-formal.

Model 1 – Tamagotchi (Status quo plus)

This path is a continuation of the school system previously accessed, where secondary and tertiary education is ideally well coordinated, so that the transfer to higher education takes place without major discontinuities. The concept supports academic orientation on the one hand and a certain degree of self-organization and independent learning on the other.

²The following sections are built upon [Orr et al. \(2019\)](#).

In this model, control and coordination, as well as the design of the degree program, are the responsibility of the respective university.

The Tamagotchi model follows the traditional concept of higher education, which is built upon the assumption that the knowledge and skills acquired at the university give learners a future-proof competence profile and enable them to adapt flexibly to future requirements.

It will have to be seen to what extent the present approach, where learning takes place in cohorts which are relatively homogeneous in relation to age and educational background, which is more or less a pre-condition for successful graduation.

Model 2—Jenga: higher education as a solid foundation for further development

In the Jenga model, higher education institutions offer a foundation of knowledge and competences, which are extended by learners through shorter study blocks in their further curricula.

Alike the Tamagotchi model, students enter universities mainly immediately after graduation from upper secondary education. Commonly, students study full-time over a couple of years gaining basic knowledge and skills. The initial university period is shorter than in the Tamagotchi model, which may be more attractive for non-traditional students, who often feel that four to five years of study are too long and/or who preferably are looking for a more application-oriented university education. From the very beginning, the model intends that the learner can and will expand his/her knowledge and competence profile through additional modules in their CVs and after interruptions. One major advantage of this approach though is that it is better targeted to *upskilling* or *side-skilling*. The former may be, but must not be, in the same or a similar direction, while the latter provides an easily accessible pathway to enter into new areas at the same level of qualification. Another option might be to gain a more “broadband” set of competences, which are deepened during a second phase or one or more additional modules.

The Jenga model addresses the concern that traditional, Tamagotchi-style, university studies are not flexible and integrative enough to be future-proof in a very dynamic environment. In an initial study phase, the basics are taught in order to supplement them later. For this model, a decision has to be taken as to what is the foundation that is needed as the basis for the beginning of a career and what should, or could, follow in later phases. Whether these basic principles are general or transversal competences or specific basic knowledge will be answered differently from discipline to discipline and from university to university.

Didactically, a basic study phase supports self-learning and self-organization, where students’ learning and personal development are oriented toward a clear learning path with defined steps and clear results. During the initial phase of study, learning takes place mainly on campus with the support of global communication networks, simulations and augmented reality techniques to extend the learning environment through online experiences. Internships, maker spaces and fablabs, help to establish early connections to the later working world. After successfully completing their studies, the students first leave the university and enter the acquisition phase. The second study phase consists of a number of learning units chosen by the learners themselves, accounting, for example, for the changing competence needs of their job. In this regard, modules can be taken at various training providers, combining on campus and/or online learning in one form or another.

While the formal recognition of the first learning phase is assured as it follows common standards, the recognition of the other learning units depends on how recognition is organized more generally within the tertiary education landscape. For learners there may be the possibility to make results-based agreements with individual higher education institutions covering both the initial learning block and the additional units. This approach is flexible as to whether learning phase 1 and learning phase 2 are integrated into a uniform study program or whether the two phases are assigned independently of each other.

The Jenga model consistently responds to the needs of students and the labor market for a study design that is better able to prepare and respond to new needs from the world of work without replacing the basic structure of a university course of study completely.

Model 3—Lego: higher education as a kit

In the Lego-model, the course of study is not completed as a compact unit as before but consists of individually combined modules of different sizes.

In this model, students are self-reliant and follow an individual, non-standardized learning path that is fully oriented toward their learning needs and interests. For this purpose, various learning units can be freely selected by the students, whether they are online and/or on-campus by different universities and new education providers. The student decides where to enroll for a module and what the topic and content of this module is, based on his or her specific needs and interests. The chain of these

learning units forms their personal course of study. In addition, the frequent alternation between phases of gainful employment and learning is characteristic of this model.

It can be left open whether there is a group of learners who study jointly and who assemble their own individual studies according to their needs or whether individual learners enroll in the modules offered. This will succeed at least for the time being in occupations in which professional qualifications are less in demand than specific skills, e.g. software development. The primary aim is to acquire knowledge and skills that can be used directly for personal purposes.

Thus, the students pull together their own study program individually from different learning units. They may be supported by employers, representatives of occupational groups (who set occupational standards) or (if available) higher education institutions (and other learning providers) who offer modules and/or learning pathways. The learners themselves are not necessarily enrolled at their higher education institution, as this is the case in the traditional system.

Ideally, the learning units account for the practical experience and the informal and non-formal learning of the students, since the time in which the students are not in formal learning environments has a significant influence on their learning behavior.

The recognition of learning modules depends on the general organization of recognition within the higher education landscape and students can enter into a learning agreement with a single institution based on learning outcomes that combines different learning units. Alternatively, it is also possible to combine learning achievements into an academic degree and have them recognized subsequently.

The Lego model closes an important gap in the traditional educational programmes of universities which, due to the dynamics of social change, are not covered by classic Bachelor programmes. The small-scale combination of different courses makes it possible to react to short-term demand and to acquire very individual qualifications.

Model 4—Transformer: higher education as an opportunity for change

The transformer model focusses on students that do not enter directly into the university as school leavers, but once they have already acquired their own professional identity and life experience, which they contribute to their studies. Thus, the time spent in school and in initial education (possibly including higher, but more commonly vocational education) is some time ago. Learners may enter into higher education for the first time or return to it either to acquire new basic knowledge and skills (*side-skilling*) or to improve the level of their formal education (*upskilling*), e.g. because of a need to change careers or the intention to acquire higher qualifications. Learners study relatively intensively over a certain period, which may have a duration of three to five years to complete their higher education studies with the expectation of returning to or re-entering the labor market. Nevertheless, it may also be possible to study for shorter periods, not necessarily heading for full qualifications. The Transformer model meets the demand of learners for possibilities of “transforming” their respective knowledge and qualification profiles.

The central idea of this model is that there should be a possibility for everyone to leave the chosen path of life and to change course. In this respect, another option for a transformation may be to enroll for an advanced vocational qualification, after a university qualification. While the latter may be less common in many countries, it may offer interesting opportunities in other countries – possibly leading to a more balanced approach between vocational and university education.

The major concept behind the Transformer model is to support learning and personal development with clearly defined steps and results. As learners do begin their university education only long after leaving the formal education system, considerable support is needed. At the same time, learners have acquired knowledge, skills and experience through their previous biographies, which they can apply to their learning. Therefore, a careful balance between academic support, guidance and independent learning with individual goals is required.

The coordination as well as the design of the study program is the responsibility of the respective universities, while accounting for the knowledge, competences and experience of the learners. However, it may be an open question for the time-being whether and to what extent previous achievements are credited and recognized. The more is credited and recognized the shorter the study courses can be. In the course of their studies, however, more and more control over their own learning path is shifted to the students, so that after an initial phase of study, the proportion of *self-regulated learning* increases.

Learning takes place mainly on campus with the support of global communication networks, simulations and augmented reality techniques to extend the learning environment through online experiences. Further learning spaces can also be integrated into the learning experience through internships, maker spaces and fablabs. Compatibility with the profession is achieved above all by extending the standard period of study and by online course units.

Change in and advancement of the labor market are essential drivers for the Transformer model, which demand either to expand competences and knowledge or to seek new fields of activity. Ultimately, a basic, occupation-oriented course of study is offered here that meets the needs of an older target group due to its flexible mediation and special didactics.

Implications on framework conditions

It appears reasonable to assume that the different new pathways presented in the previous sections may demand different ecosystems, particularly in relation to funding models as well as student support, since most models so far refer to standard types of full- or part-time studying. While fee systems are often responsive to part-time students, e.g. by adjusting the fee rates, more or less, this is less the case for student support schemes. Yet, the more flexible study pathways and the demand for learning modules are, the more flexible funding models for universities and student support need to be, provided that the state plays a certain role in it. Or: as far as state funding is concerned.

When looking at funding models for universities one should distinguish between state funding to universities and individual student contributions, i.e. commonly fees. As far as we can establish, present public funding schemes for universities are either supply-side and/or different types of demand-led funding. Often, funding still largely refers to inputs, staff and other investment and recurrent expenses, addressing the fact that those have to be covered. In other cases, lump-sum payments or block grants account for certain shares of the costs, demanding from the university to generate additional funds to cover the full costs of operation, including fees. Performance-based funding addresses different types of input and/or output indicators for learning and research etc. to stimulate better performance.

Whatsoever the specific type of funding, they address different learning pathways more or less, commonly less – though this depends also on the specific approach to studying. If supply-side funding is employed covering the total costs of operation and not accounting for different types of students, e.g. part- vs. full-time or incoming and outgoing students etc., it is not very important what students do in practice, i.e. whether they attend courses more or less frequently or not, unless this does not overstretch the courses offered and the number of students per course foreseen.

More or less, the same applies to block grants and performance-based funding, if concrete individual demand is not accounted for. Only if funding depends on concrete demand, e.g. work load by number of courses, hours of course attendance or study credits demanded (e.g. based on ECTS).

From the students' point of view, the same applies, s/he can attend a certain number of courses or run for study credits etc. However, the amount of fees to be paid may matter, if fees are responsive to full-or part-time study, etc.

Yet, the funding regime might be challenged in case of the Lego model, where students enroll on a module or course basis and intend to demand only a small number which is below the official figures for part-time study. S/he may prefer to pay less, while the university may be reluctant to respond to this request. Whether or not the university may be responsive depends on different factors, e.g. the nature and design of public funding and the type of incentives implemented. Incentives to be responsive may be stronger in case that funding follows student and the number of modules or courses³.

A funding model that is fully responsive to very flexible individual study modes has been designed by Dohmen (Dohmen, 2003a,b). It aims to be neutral to different types of individual study modes from the viewpoint of the students, while providing an incentive for universities to enroll as many students as possible, till maximum capacity is reached⁴.

This funding model is based on the number of European Credit Transfer System (ECTS), which have to be acquired for a Bachelor or Master's degree. By the time of drafting, 180 ECTS were the standard norm for a Bachelor degree and another 120 for a Master degree, at least with regard to Germany. Thus, the student's learning account had 180 or 120 ECTS (plus x for some repetition or additional modules, if applicable). If the student enrolled for a module, the corresponding number of ECTS would be deducted (for example, half at the beginning of the module, the rest at the end) and the university received the corresponding amount of money, which should be responsive to full-costs coverage for a specific, standardized number of students per program or module⁵. The funds allocated were recommended to be responsive to the average costs of the programmes, i.e. commonly higher for STEM or medicine than for Arts and humanities, economics etc. This approach meant neutrality in relation to subjects as well as study behavior – allowing also for competition between the departments of the university or between universities. The learning account enabled the student to enroll in one German university for Module A and in another German or foreign university for module B and to spread the study program over as many semesters s/he wanted. In this sense, it would be fully responsive to all study models and learning pathways presented above – it would be particularly applicable to the Lego model, which is the most flexible one.

More precisely, the advantages of this approach were: (a) students are free to decide when and where to enroll, to study (temporarily) full-time and/or (temporarily) part-time and to what extent they wanted to study part-time, (b) the model was neutral and allocative efficient in relation to total public funding and (c) provided an incentive for the university to exploit its full capacity.

³The core discussion on „money follows students“ refers to the number of students at a university, but less to the amount of modules or any other type of workload (Musset, 2012).

⁴It might be worth, though, to point to the issue that overall upfront and step-fixed costs play a strong role in education, while marginal costs are often very low, if not even nil (Dohmen, 2015).

⁵It should be noted that a trade-off exists between a more general and a very specific funding approach and that universities have to recoup the full-costs of each program, module as well as at full-scale, at least, to avoid loss and bankruptcy (Dohmen, 2015). This suggests that certain lump-sum figures should apply, which allow full-cost coverage, even though this may not be fair for any single case.

While the model had been initially designed for the German university system in two states, it was eventually implemented in Switzerland to finance the Universities of Applied Sciences.

One may discuss whether student support schemes should be similarly flexible or not, and to what extent this is necessary to target students from lower socio-economic backgrounds. While full-time studies would have to be linked to a proper student support scheme, independent from age, this is less clear in relation to part-time studies, which may go along with part-time employment. However, as part-time employment does not necessarily result in an income that allows to cover the costs of living, particularly if the student has children or a financially-dependent partner, it seems advisable to make student support schemes fit for part-time students. It can be means-tested and/or be provided as an interest-bearing loan.

A key requirement for student support schemes is that they are less age restricted as presently the case (FIBS/DIE, 2013). Most student support schemes target more or less exclusively young adults, though different age limits apply. The more such support schemes address the Tamagotchi model, the more they target very young students, while they are less responsive to the Jenga or even Lego-model. More precisely, the target group of most support schemes are people till the mid or late twenties, studying full-time. Examples in this respect are the Dutch or some South-European models, but also the German BAfoeG, even though the latter is open to students enrolling for the first time at age 30 for a Bachelor program or even 35 for a master program. These models address equality of opportunity and help students from low-income families to overcome funding bottlenecks of full-time studies.

While these models may even be satisfying the needs of the Jenga- or Transformers model, provided people start studying within certain time or meet the age restrictions frames, they are particularly not supportive to the Lego model, as this is far more flexible.

While some funding schemes as well as student support are open to older students, as for example the Higher Education Contribution Scheme in Australia as well as the funding model in Sweden, they still are not fully responsive to the very flexible study model of Lego (FIBS/DIE, 2013).

Colleges and universities contribute to the preservation of the past and the invention of the future. The classroom and the library, actual and digital, are still the essential locations for postsecondary education. Indeed, for centuries the library supported knowledge seeking and making as its essence, a place where the world and experience could be studied with the print record that spanned centuries. But it is the rare scientist or scholar who visits the library today except on a screen. Digitalization has meant the near total revision of how information—in journals, books, and other resources—is gained, used, maintained, and circulated. Accordingly, as colleges and universities find new ways to advance their educational missions, there are unanticipated forms and roles for scholarly communications, now understood as a global digital system for the exchange of ideas and practices across the many disciplines of academic inquiry. Indeed, with due regard for the impact of technology on teaching, scholarly communications has been characterized as higher education’s “real digital change agent” to encourage recognition of its likely long-term and profound influence on the university as an institution (Mittell, 2013).

Open access “Takes Flight”

Scientists and scholars have recognized in recent decades exponential growth in academic publishing. There is no exact figure to represent the explosion of knowledge but an authoritative estimate claims that about 3 million academic articles appear annually in about 42,000 journals, more than three-quarters of them in English (Johnson et al., 2018). It is no surprise that there is so much interest in the problem of information overload, though it would be a mistake to think that it is unique to our time (Blair, 2010). Indeed, a taste for knowledge means attention to scholarly communications. It may not be a subject for commencement addresses but a recent film—*Paywall: The Business of Scholarship* (freely available at paywallthemovie.com)—shows the impact of the high cost and thus exclusionary subscription system of academic journals. Access to what scientists and scholars wish to read is essential to the faculty’s productivity and to professional identities.

The faculty and the library have been allies in their interest in the steady expansion of science and scholarship. Alas, scholarly publishers, chiefly a small group of highly profitable corporations who supply most academic journals, all in Europe and North America, have turned out to be antagonists to both, principally in what they can demand in online subscriptions. After all, each journal is unique and likely indispensable to some number of scientists and scholars on campus. The library cannot go down the street in search of a better price. What came to be known late in the last century as the “serials crisis,” or the nearly annual increases in subscription costs, signified the fragile financial status of libraries at institutions of all kinds. The strategy known as the “Big Deal,” devised by publishers, only exacerbated the problem, forcing libraries to buy many more journals than they desired in order to gain a better price on the most necessary. And negotiating on their own with publishers left libraries vulnerable and without the prospect of achieving cost effective ways for the faculty to gain access to the journals they relied on.

There were other widely recognized problems with the system. The traditional subscription structure left struggling and new institutions in poor parts of world with only the most limited access to the journal literature at a time when global academic aspirations were increasing. But a fortuitous gathering in late 2001 (as below) took a fresh look—philosophically, institutionally, and economically—at the conditions of scholarly communications and recent digital publishing experiments. They proposed in “Open Access” (OA) a new format for dramatically improving online availability of what scientists and scholars (and others interested in academic work) want to read. Two decades of proposals, initiatives, and new experiments followed. In 2021 UNESCO made its enthusiastic “Recommendation on Open Science” (endorsed by all 193 member states) and the influential journal *Science* reported that the Open Access movement had “taken flight” (Brainard, 2021). It cited the European Commission’s *Plan S* project, with its broad OA mandate, as primary evidence (coalition-s.org; Else, 2021). Not all nations joined the *Plan*. But the steady growth in OA journals and articles, if not yet in books, signified enough for *Science* to speak confidently of hopes for “upending” decades long traditions in scientific and scholarly publishing. Indeed, in 2017, for the first time, most new papers (as usual the vast majority were in science), were published as OA.

Open Access is now a permanent part of the higher education and scholarly communications landscape boosted, to a degree by the COVID-19 pandemic and the urgency it has meant for access to the latest research on vaccines, drugs, and the social and economic dimensions of the global health crisis. Still, as a 2018 statement by a group including participants in the institutional origins of OA makes plain, there are significant obstacles remaining before it becomes the default format in scholarly communications (Shockley et al., 2018). The response in publishing to the pandemic has had a positive if still uncertain lasting meaning for OA (Lane and Lifshitz-Assaf, 2022). There is recognition of the potential for a pandemic inspired “new normal” (Brainard, 2021). But even as an unfinished project in higher education OA is having a significant impact on publishers, libraries, and research funders, and on scientists and scholars hoping to make the most of the digital transformation of inquiry.

The goal of subsequent sections of this chapter is to add to the success story told by *Science* with recognition of what still requires attention if “open” is indeed to become the common condition in science and scholarship everywhere. The chapter begins with an account of the beginnings of OA including the allied phenomenon of repositories, now viewed as indispensable to the OA movement. But as the advent of Plan S suggests, the long term fate of OA will reflect the uneven participation of authors, the subject of the next part of the chapter. There follows attention to an important obstacle to OA’s success, the limits of its impact in the Global South, particularly Africa. The next part looks at the meanings, in the context of the rise of OA, of the steadily rising volume of scientific and scholarly publishing—an unwelcome development for some critics, including what it says about the allocation of faculty resources for teaching. Thus, the future of OA, as the chapter’s conclusion indicates, is by no means assured, at least as it was originally envisioned, and most of all outside the well resourced Global North. OA may have “taken flight” but its trajectory is still incompletely understood. It is an unfinished project.

Transformation by declaration

Open Access as a movement in scholarly communications began in late 2001 with a meeting in Budapest of sixteen librarians, scholars, foundation and academic leaders, technology professionals, and others. The Budapest Open Access Initiative (BOAI) was sponsored by the Open Society Institute (headquartered in Budapest) which became an important source of support. The brief statement, or “Declaration” (www.budapestopenaccessinitiative.org/read) announcing the goals of OA that came from the unusual meeting is little more than a page but it is rich in ideas about higher education and journal publishing, particularly what makes access to articles so costly and what adjustments must be made in the global scholarly communications system to gain more accessibility and to maintain high standards of inquiry.

Peter Suber, who has headed Harvard University’s *Open Access Project* (cyber.harvard.edu) for many years, participated in the Budapest meeting and (according to others) wrote the Declaration. There is an artful opening sentence: “An old tradition and new technology have converged to make possible an unprecedented public good.” In other words, the habits of scholars who freely contribute their work to journals are to be joined to what is made possible with low cost digital publishing. The first paragraph of the Declaration also reflects the idealism that still characterizes the OA movement. Thus, “Removing access barriers to this literature will accelerate research, enrich education, share the learning of the rich with the poor and the poor with the rich, make this literature as useful as it can be, and lay the foundation for uniting humanity in a common intellectual conversation and quest for knowledge” (BOAI, 2002).

The Declaration offers this as the core of its definition of OA: “By ‘open access’ to the [scientific and scholarly] literature, we mean its free availability on the public internet, permitting any users to read, download, copy, distribute, print, search, or link to the full texts of these articles, crawl them for indexing, pass them as data to software, or use them for any other lawful purpose, without financial, legal, or technical barriers other than those inseparable from gaining access to the internet itself.” The last, alas, remains a problem in some parts of the world even twenty years later. Suber (2012) himself now often uses a more compact definition of OA: “Open Access literature is digital, online, free of charge, and free of most copyright and licensing restrictions” (p. 4).

Subsequent meetings (in Berlin and then Bethesda, Maryland) produced allied declarations. But the differences were reconcilable enough for Suber to sometimes refer to the “BBB Definition of OA” (p. 7). His most recent contribution to the OA movement is leadership of the project (in progress in 2022) to identify “Good Practices for University Open-Access Policies” (cyber.harvard.edu/hoap/Good_practices_for_university_open-access_policies). The phrase “good practices” rather than the ubiquitous (in higher education) “best practices,” signifies that on many points in the guide there are differing views among those contributing to it. Thus, “there can be wider agreement on which practices are good than on those which are best.” And “Good practices change as circumstances change” (Schieber and Suber, 2021).

But it is not only “practices” that diverge. At the Budapest meeting participants disagreed about what might be expected of the different interests in OA reform. It appeared that the group was seeking to speak mainly on behalf of scientists and scholars and prospects for improving communications among them and with others. But publishers, librarians, and professional associations (many with major investments in their journals) also had needed attention. At the 15 year anniversary of the BOAI Jean-Claude Guédon (2017), a Canadian scholar of information science who participated in the Budapest meeting, surveyed the OA landscape and found problems faced by the movement as important as its notable achievements. His extensive survey was published (at its website) by the BOAI, signifying its role in realizing the goals over the long term (other recent surveys include Pinfield et al., 2020 and Eve and Gray, 2020).

Guédon restates Suber's now well known image: "Open Access is simply a way to express the cross-fertilization of the very essence of science with new technologies to create the optimal communication system science needs" (p. 2). For Guédon, in the time since the Budapest Declaration a configuration of forces has kept the "optimal" at a distance. Chief among them is the oligarchical behavior of the leading commercial publishers (Lariviere et al., 2015). In effect, seeing academic journals as merely "commodities" they have focused on business models with the highest yield to investors. These came to include the notorious "Big Deals" with academic libraries and, most recently, the system of Article Processing Charges (APCs), a strategy designed to represent the publishers' version of commitment to OA while protecting their financial interests. Publishers have stood by the costly (to authors and their institutional sponsors) and journal-based "Gold OA," leaving a competing way of managing OA, the repository-based and generally free "Green OA," to non-profits like libraries and professional organizations.

In effect, policy making about OA, and scholarly preferences and practices, have organized around such a binary, one that had in fact been anticipated in the Budapest Declaration. But the differences between the two, complicated by both faculty inattention and, for some, loyalty to the traditional journal system and its measures of achievement (the well known "Impact Factor") have left publishers with sizable financial advantages. Academic libraries and repositories have suffered in recent decades along with their host institutions as budgets for higher education, apart from the highest ranking universities, have declined or barely kept pace with inflation.

In Guédon's analysis, genuine global OA, however well timed from a scientific and intellectual point of view—or as a force for the "public good"—fought an admirable battle against international conglomerates. Progress in OA has been substantial. By 2022 the *Directory of Open Access Journals* (DOAJ) had listings of over 17,000 journals (from over 130 countries and in 80 languages) with over 12,000 without APCs. Article records are far beyond seven million. But the competition for legitimacy in OA goes on. APCs, and enough compliance from scientists and scholars with their institutions, have allowed the publishers' business models to continue to forestall any alternate set of values for the dissemination of inquiry. Thus, the present system of journals, particularly those using Gold OA, obscures their profit making habits. "Together, these journals are engaged in an endless system of competition that is supposed to energize research globally, and serve its intrinsic objectives. In actuality, the system acts as the pressure system that, in rich countries, keeps armies of scientists in line" (Guédon, p. 38).

For Guédon, science and scholarship themselves must be at the very center of communications practices displaying the powerful effects of digital culture and the strength of networks. "In no case should economic interests be allowed to interfere with the full potential of a free communicating system designed and destined to help humanity—the whole of humanity—grow knowledge" (p. 38). In effect, OA is presented in this recent account of it as an educational project, as new knowledge is negotiated among scientists, scholars, and students. In the new digital configuration the library, still constrained by commercial publishing, plays its traditional educational role in providing many of the necessary resources for study as well as helping to advance the goals and practices of OA.

arXiv and after

As a cross disciplinary digital initiative Open Access is justifiably recognized as a groundbreaking innovation. But an important predecessor was already a decade old when OA was launched in Budapest. The universally popular (among scientists) website arXiv began in 1991 at the Los Alamos National Laboratory in New Mexico and since 2001 has been at Cornell University. The best known of the pre-print servers, arXiv represents how academic communications changed with the advent of the Internet, and how scientists adapted to new conditions of communications with widespread participation and enthusiasm. The OA site now serves physicists, astronomers, mathematicians, computer scientists, quantitative biologists, statisticians, and others. MedRxiv (founded in 2019 by the famed Cold Spring Harbor Laboratory in New York) aims (with others) OA resources at the health sciences, while additional new disciplinary repositories serve scientists in the prompt circulation of their research in the new format. MedRxiv became indispensable in the years of COVID-19.

In effect, seeking to keep their fields as up-to-date as possible, many users of sites like arXiv and medRxiv now bypass at least temporarily the conventional system of scientific journals to communicate directly with one another. They do so with what were at first called "e-prints" and now "pre-prints," or pre-publication versions of journal essays. For physicists and others pre-prints are as important as what might appear later in formal publications. And a significant number do ultimately appear in journals. But many valuable contributions to physics and other fields do not—their permanent research home is the freely accessible platform. At the site arXiv refers to itself as a "highly automated electronic archive and distribution server for research articles." Such a simple statement may obscure what has been termed "transformative" about the OA pre-print movement in scholarly communications (Chiarelli et al., 2019).

Submitting pre-prints to arXiv and similar sites requires "endorsement" by a disciplinary colleague. The site is "moderated" only to guarantee that submissions are relevant and their research methods responsible. But what appears at the site is not peer reviewed in the traditional sense. Thus, arXiv is an early example of the approach called "publish first, filter later" according to principles of open access. By 2022 arXiv had registered over two million submissions and downloads had passed two billion. The success of arXiv has prompted many institutions to establish similar sites, often called "repositories," a term also used by

countless colleges and universities around the world to name an institutional site, typically managed at the library, for housing digital documents. Ideally it features articles by faculty members but it can also include syllabi and many other kinds of resources of potential interest to scientists, scholars, students, and the public. In 2022 over 6000 OA repositories were registered at OpenDOAR (the Directory of Open Access Repositories; v2.sherpa.ac.uk/pendoar). As a global phenomenon they represented institutions, associations, and organizations of many kinds and different ideas about what is worth collecting, preserving, and disseminating (Arlitch and Grant, 2018).

The communications situation has been slow to change in fields other than scientific ones. For example, until recently in literary and language studies scholars had nothing like arXiv to centralize their efforts and to speed the pace of interactions among authors and readers. They could submit work to the comprehensive Social Science Research Network (now owned by the publishing giant Elsevier) a location used by scholars in over twenty fields. In 2016, however, the Modern Language Association (MLA) opened the Humanities Commons (hcommons.org) to provide a more specialized space for self-archiving, as some like to call it, based in literary studies but including allied fields. It is now based at Michigan State University in the United States. An account of OA by the Brookings Institution (US) reflects hopes for the expansion of the format into all disciplines (Lane and Lifshitz, 2022).

Some might say that speed, a frequently cited feature of OA publishing and pre-print servers in particular, is hardly vital to philosophers, art historians, scholars of French literature and others in the humanities. A former scientific director at arXiv has said that the site “accelerates the pace of science by allowing researchers to get material out there for others to see and build upon right away. It’s the go-to source, the core of an ecosystem, and it fills critical research needs for researchers around the world everyday” (Cornell Chronicle, 2015). The new field of Digital Humanities represents a change in the pace of research and thus the desire for OA. But the humanities generally, and a good share of the social sciences, have different digital needs, reflecting different information practices, than do the fields represented at arXiv. It took some time in the humanities to find a suitable structure. A distinguishing feature of the Humanities Commons is that it is a non-profit OA resource and social networking platform run by scholars themselves. It is utterly unlike the venture capital supported and for profit repositories and social media platforms academia.edu and [ResearchGate](https://ResearchGate.net).

Whatever its role in launching a revolution in how a field can organize its communications, arXiv demonstrates what more might be done. For its founder, physicist Paul Ginsparg—still an important voice in the transformation of scholarly communications—there was a time when faculty work was part of the pioneering spirit of the Internet, new developments being “naturally adapted” to research. In 2006 Ginsparg thought it likely that within a decade “more research communities will join some form of global unified archive system without the current partitioning and access restrictions familiar from the paper medium, for the simple reason that it is the best way to communicate knowledge and hence to create new knowledge” (p. 9607). But, for Ginsparg, to the degree that commerce and entertainment came to dominate the Web, academic interests (like OA) were lagging in innovation. Oddly enough, the unadorned arXiv in 2022 looks hopelessly out-of-date as an Internet resource. Many first time visitors are surprised and pleased by its simplicity or disciplined functionality. But, as a pioneer in OA it still stands for an approach to research and communications that couldn’t be more timely or user friendly. Hence its utility as a model during the COVID-19 pandemic and, for some observers, far beyond.

Nonetheless there are those who wonder about whether the highly decentralized or even fragmented institutional repository scene isn’t an obstacle to realizing the global goals of open access. Many authors are reluctant to participate, preferring, despite the cost, to have the advantages in visibility and reputation of the Gold OA system with its APCs. Mandates for OA from government agencies and private funders are nominally neutral about where work appears. But for many scientists and scholars the stakes are too high to rely on repositories, still awaiting interoperability and other features of the traditional system of dissemination offering inclusion in leading indices and thus visibility, or discovery (in the vocabulary of the library) and what follows in citations and then academic rewards. Thus, while the disciplinary cultures served by arXiv can capitalize on its reach, reflecting high levels of participation, contributors to the Humanities Commons must await confidence in discovery and impact. The problems are compounded by competition from institutional repositories (at postsecondary institutions) which offer even weaker prospects for both. Important early supporters of such repositories see them facing an “existential crisis” in the years ahead (Poynder, 2016). Some academic librarians favor a national level repository but do not see their colleagues as willing enough to collaborate to make the most of “network effects” (Arlitch and Grant, 2018). The same might be said for other problems and opportunities facing higher education.

Faculty responses to OA

Judging from its high rates of submissions and downloads (reported daily at its site) arXiv is part of the workday of a sizable number if not most physicists around the world. But for scholars in many fields there is not yet the habit of capitalizing on OA in any of its formats. As the latest Ithaka S+R faculty survey showed there is increasing enthusiasm for the conversion of the publishing system to OA reflecting the advantages survey respondents find as readers. But, thinking as authors about what they face at present in the academic rewards system, only 40% of respondents said that they pay any attention to OA in considering where to submit their work (Blankstein and Wolff-Eisenberg, 2019). How much the pandemic may change such views is something that future studies will record.

Open access has its faculty champions, those hoping to make “open” central to the evolving academic vocations and postsecondary educational professionalism. Martin Weller has been associated for many years with Britain’s Open University, the pioneering public institution of its kind. He has impressive experience in the design and assessment of online teaching and learning, particularly according to emerging norms in “open” education, or online degree programs organized for the greatest possible access. Weller moved beyond the instructional dimension of electronic change in education in his book of 2011, *The Digital Scholar: How Technology is Transforming Scholarly Practice*. He embraces the newest technologies and adapts innovations for broadening communications in order to build new communities of inquiry. Weller focuses on three conditions of “transformative practice” in scholarship and science: It is digital, networked, and open.

For Weller, a “digital scholar” is above all a social one, giving priority in his or her work to the professional connectivity provided by the Internet, and, in the spirit of OA, to “participation” by anyone with views about the topics in one or another field of science and scholarship. Expert knowledge will certainly have a role in participation in many subjects. But participation itself, and thus the democratization of knowledge, remains a core principle in the world of the digital scholar.

In the decade since *The Digital Scholar* OA has continued to expand its reach as is evident in the record of the DOAJ and OpenDOAR. While it is still far from having fully altered the influence of the major commercial publishers, convinced all scholars and scientists of its virtues, and helped to close the gap between rich and poor countries in scholarly communications, OA has indeed, as *Science* asserts, “taken flight.” And there has been a steady increase in citation rates for OA articles. By 2018 they were being cited 18% more often than paywalled ones (Piwowar et al., 2018).

Still, according to Guéron (and others) scholars and scientists themselves have played only minor roles in the conceptual and organizational development of OA. Plainly researchers are at the heart of scholarly communications. They provide their articles and books, and evaluate the work of others, as part of the publishing process. They communicate with one another but it is in a communications system they do not control. For many that means they pay little attention to its structure and debates, including the steps that have been taken among publishers, libraries, and funders to respond to the BOAI of 2002 (and later declarations). “The shaping of the future of science communication was not always in the hands of those who needed it most to communicate and work” (p. 8). Guéron believes that whatever the system does to support the “grand conversations” of the disciplines, as has long been said, it also “acts like a powerful tool to manage careers and reputations” often indifferent to the wishes of participants.

Thus, scientists and scholars are still prompted to focus on the misleading “impact factor” as the essential metric, the competition among journals for prestige, and the academic rewards to individuals that flow from publishing in the highest ranked outlets. OA is often perceived as lacking in the status most want for career advancement. And, alas, there is cooperation with the ultra-competitive publishing system by academic leaders, including colleagues serving in evaluation roles for promotion, tenure, and annual review who defer to the most conventional standards of research productivity. Moreover, despite the number of repositories there has been only limited faculty participation even with institutional and government mandates (Tmava and Miksa, 2017). Guéron concludes that “most researchers, although deeply dependent upon the system of scientific communication, are probably among the people that understand it most superficially—certainly more superficially than librarians and publishers” (p. 29).

True enough, the scale of contributions to OA megajournals like PLoS ONE is impressive even with declines in submissions (Brainard, 2019). But recent studies of faculty attitudes toward OA in all formats—when they are even aware of it—confirm the Ithaka S + R findings and demonstrate that the movement will require perseverance if it is to take hold broadly among scientists and scholars (Fitzgerald and Jiang, 2020; Dalton et al., 2020). What will convince more faculty to publish in OA journals and to submit their work to repositories? All authors want their work read and used. And the early record for the transition to OA publishing is promising as journals themselves, from the influential commercial giants (building the case for APCs) to the newest entrants in scholarly communications support the format. Academic libraries seek to educate the faculty, largely via their websites, about obligations (in mandates) and opportunities across the different forms of OA. Postsecondary institutions have roles, particularly in the making of policies for tenure and promotion and other academic rewards. But these rarely address the changes introduced by digital publishing, including the growth of OA.

For learned societies the new terrain of scholarly communications has prompted both enthusiasm for OA and anxiety about its impact on association sponsored journals (Wise and Estelle, 2019; Harrington, 2019). Thus, new organizations, like Transitioning Society Publications to Open Access (tspoa.org), are guiding stakeholders toward a level of transformation that suitably represents (in the vocabulary of the Budapest Declaration) the old and the new. Inevitably Plan S, with its far reaching mandate and urgency, has complicated the transition and prompted some learned societies (like the American Historical Association) to protest its impact on publishing in the humanities. In effect, scholars and scientists having to respond to the phenomenon of OA must navigate a system being reconfigured by interests that are not always complementary.

Journals, of course, do not exhaust the publishing plans of scholars. Still, this chapter, as does most work on OA, features its impact on serial publication, particularly in the sciences. The Directory of Open Access Books (www.doabooks.org) shows steady growth in recent years with (by 2022) over 51,000 titles from over 654 publishers. A study of OA books showed that authors are uniformly supportive of them for the visibility they give their work. The format lacks only greater institutional support and publisher’s receptivity to make it routine (Pyne et al., 2019).

There are now underway allied projects seeking to aid libraries and university presses in OA initiatives making books in the humanities and social sciences discoverable and useful. *Knowledge Unlatched* (knowledgeunlatched.org) uses funds contributed by libraries to bring OA monographs into collections in many nations. *Toward an Open Monograph Ecosystem* (TOME; www.openmonographs.org) is a collaborative book subsidy project of the Association of American Universities, Association of Research Libraries, and Association of University Presses. And the Andrew Mellon Foundation supports the development of platforms for multi-media OA monographs at US university presses (e.g., [Kasprzak and Smyre, 2017](#)). An account of new forms of inquiry in the humanities reflecting such projects displays satisfaction in OA for what it can yield for the scholarly vitality of academic authors ([Scarborough, 2021](#)). Similarly, a recent report on *The State of Open Monographs* urging the expansion of the OA landscape foresees the innovation's fruitful influence on the form of the monograph and the "ironclad" role of the traditional book in the academic reward system ([Grimme et al., 2019](#)).

The global gap

As *Science* suggests, a satisfying story can now be told about Open Access. But how far does it extend beyond European and North American research toward making "bibliodiversity" an essential feature of OA ([Berger, 2021](#))? Latin America offers a promising recent history in OA. In contrast to the European and North American deference to the major publishing corporations organizations in Latin America have built a non-commercial OA infrastructure. Called an OA "ecosystem," five publishing platforms provide software applications, interoperability, visibility, and discovery for Latin American research output ([Lopez and Garcia, 2019](#)). The group has opposed Plan S and the prospect of APCs, registering its OA experience: "When opening access is decontextualized from its historical and political roots, it has the potential to become as exploitative and oppressive as the system that it seeks to replace."

As part of a recent forum on global trends in OA, Vrushali Dandawate, an Indian librarian and also the DOAJ Ambassador for India and Pakistan, reported that while there are over 3600 Asian journals listed in the Directory and over 1200 Asian repositories registered in OpenDOAR, government and faculty indifference, particularly to mandates, has limited their utility ([Harris, 2021](#)). That has made the work of individual OA advocates crucial but the effort is fragmented, with limited regional interaction and collaboration. Indeed, only a small number of countries in the Global South (four in the classification presented by Prost and Schöpfel in [Herb and Schöpfel, 2018](#)) produce enough research or support enough repositories to make likely partners in international OA projects.

Scholars have for two decades lamented the great gap between OA resources and practices in the Global North and Global South. Early in this century the World Bank and the World Health Organization mounted projects supplying online access to journals, however much the lack of suitable digital infrastructure limits their uses. And even when private philanthropy helps with OA in Africa it can display what can be described as "neocolonial" habits. Thus, Florence [Piron \(2018\)](#) reports on a visit to the library at a Sub-Saharan university which had been awarded support for OA by an international organization. But the library was denied the choice of the journals it could access, being limited to what the project specified. And, as Piron shows, the local infrastructure was hardly improved: "The program had installed two computers providing access to its journals. However, to prevent unauthorized access, these computers were protected by passwords that changed every month! At the time of my visit, the librarians had lost track of these changes and, as a result, [the] new computers were unusable" (p. 122).

Other observers of the operations of OA in Africa see a pattern of neocolonialism, or the "corporate capture" of research with far reaching consequences (e.g., [Meagher, 2021](#)). Cameroonian scientist Thomas Nkoudou, following Dandawate in the online forum, acknowledged that the OA situation in Africa was improving but he was precise in specifying practical problems: "The challenges open access is facing in Africa are physical barriers with electricity issues, lack of access to equipment, internet connectivity, and the lack of infrastructure. We also have cognitive barriers, because a lot of people still lack skills related to open access, even sometimes librarians, and people are still alienated by the Impact Factor and university ranking" ([Harris, 2021](#)).

For Nkoudou two metaphors represent the fate of OA in the Global South. One is familiar. Thus, Europe and North America "sit at the center of the system, and countries of the Global South, are placed at the periphery." They are allocated resources and services accordingly, more often made objects of "knowledge philanthropy" reflecting how Western institutions and corporations understand their needs rather than being invited to collaborate in attention to local interests ([Sengupta, 2021](#)). Stating what he sees more dramatically, [Nkoudou \(2020\)](#) offers another binary, based on the classical Greek *pharmakon*, a medical ritual that sometimes cures and other times acts as a poison, (pp. 25–26). He fears widespread "alienation" among scientists and scholars from local cognitive traditions and research habits.

The pace of digital change puts fresh pressure on all stakeholders in the OA movement. The change is at a scale that requires cultural as well as digital transformation. In her account of the interactions of the two, long time publishing consultant Lettie [Conrad \(2021\)](#) focuses on the rapidly evolving OA activities of major publishers who "have been metamorphosing before our eyes, shedding old ways of doing business and taking up broad initiatives to reinvent what publishers do and why they matter." But in recent years, scholars of the Global South, including those who live and work there (like Nkoudou), have asked if there has been sufficient change in attitude to go with the redesign for OA of the international publishing system. According to Conrad "digital innovations are more of a human science than a computer science." She welcomes the claim from one of the large German

journal publishers: “The consumer and their information experience is at the heart of all decisions.” Such a stance presumably protects publishers, as Conrad puts it, from a “disconnect between the overarching [industry wide] narrative and the reality of what is being built.”

Looking back at the Budapest Declaration, and the many similar expressions of OA solidarity that have followed, including most recently from heretofore resistant but still increasingly profitable publishers, Nkoudou finds such a “disconnect” between “good intentions” and the “realities” of OA adoption in Africa. Since 2002 “OA has evolved positively but has also been deeply perverted,” largely by the introduction of APCs in Gold OA, as a “vehicle of continued exclusion” (pp. 28–29). They are far beyond the reach of African authors and institutions, even when (at times) partial waivers are applied. Conveniently enough for publishers, APCs “consolidate their market strategy” at the expense of attention to ideals of truly open knowledge dissemination. Worse yet, the current system, with its ill effects on African science and learning, yields “epistemic alienation,” or “the distortion of one’s native way of thinking, and of seeing and speaking of one’s own reality” (p. 32).

Nkoudou has practical and philosophical steps in mind. For Africans, “Failing to embrace OA would mean missing a significant opportunity to improve dissemination, visibility, and the impact of research findings from the African continent” (p. 35). There is more to the dissemination of knowledge than the traditional, published journal article (and Gold OA with its high APCs). Instead, Green OA, as in the uses of repositories, can support the rich “gray literature” like theses, dissertations, and research reports that are available in Northern databases (see also [Adam and Kaur, 2021](#)). There has been some progress. *African Journals Online* ([ajol.info](#)) now shows 306 online journals among the 583 at its database. But more than half of the nations with journals at the aggregator contribute three or fewer. Can they increase OA participation? Perhaps the best path, barring transformational reform among the major publishers, is adopting the organization of OA in Latin America, where scholars, scientists, and institutions themselves, with support from national governments, design and manage OA initiatives.

Anthropologist Mahmood Mandami, who has spent more than a decade at Makerere University in Uganda, sees the significance of OA in Africa historically. Colonial powers believed that the only valid learning was created in the West, needing only distribution to other regions. “It is time that we put a stop to this idea that Makerere and other African universities were created as centers for knowledge dissemination and not knowledge production” ([Agaba, 2022](#)). OA makes all nations potential distributors of knowledge. And the conditions of digital publishing, particularly OA, means opportunities in fields often neglected in graduate education and research in the developing world. According to Mandami “Our threat is a leadership which is infatuated with technology and which thinks that you do not need the humanities and social sciences, that all you need are engineers and doctors. We need to put aside the question of narrow specialization [because] it leads to a dead end [by] focusing on means and methods and not on goals.” Of course, OA also contributes to information overload. Speaking for scholarly communities preparing for participation in the emerging open system Mandami reminds them that “Not everything that anybody says or thinks should be published.” While it builds local OA participation, African scholars and institutions should be providing for debate as well as distribution.

To be sure, the problem remains of increasing recognition from scientists and scholars of the value of Green OA, including what uses of it can contribute to a more inclusive science. Seen this way, OA is a resource in the “quest for epistemic freedom or the right to think, to theorize, and to interpret the world; to develop one’s own methodologies, and to write from where one is located, unencumbered by Eurocentrism” (Nkoudou, p. 36; see also [Herb and Schöpfel \(2018\)](#) for a timely collection of articles on OA written in this spirit).

John Willinsky (2006) in his influential early account of OA, also acknowledged efforts around the time of the Budapest Declaration to improve the provision of OA in Africa. He spoke for “a far more distributed journal culture to spread through the academic community, against an otherwise centralized model” (p. 108). But he also anticipated Nkoudou and others looking at OA in the Global South today in recognizing “risks” in simply delivering more and more Western OA research. Willinsky asked: “Can technology indeed help rewire not only older patterns in the circulation of knowledge but the spread of education and the growth of research capacities?” (p. 109). If it can, then a strong local educational system can produce knowledge representing its own interests and methods. Willinsky urges recognition of what scholars in the Global North can gain from visibility (via OA) of the work of colleagues in Africa and elsewhere (see also [Bwalya and Akandelwa, 2021](#)). In *The Access Principle* (2006) he cites the Sri Lankan literature professor Suresh [Canagarajah \(2002\)](#) who says that “an engagement with local knowledge from peripheral contexts can help enrich, expand, and reconstruct mainstream discourses and knowledge” (p. 107).

How much publishing is enough?

However much the major publishing companies are leaving Open Access as unfinished in some parts of the world they have responded robustly to OA within the Western system, largely by becoming advocates for it, if on their own terms. Thus, national and local mandates are matched by new business models (e.g., “transformative agreements”), largely leaving in place the high profit margins the publishers have enjoyed for decades ([Hinchliffe, 2020](#)).

Despite the geographical “disconnect,” the reputation of OA is stronger now than ever. It is helped along by the fact that the volume of published work, from excellent to mediocre and worse, continues to increase at a high rate ([Génova et al., 2016](#)). Of course, a good deal of that reflects the ease in establishing electronic journals, at least in comparison to the demands of traditional print.

Inevitably, critics of academic publishing, finding too much of it, take the values of “publish or perish” and the expansion in opportunities it has prompted as the primary causes. Philip Altbach (2019), long an influential scholar of higher education, recently offered (with Hans de Wit) a brief but powerful statement of the problem, claiming that “the publishing system is out of control.” But even in the early days of the application of digital technology to scholarship there were those who were worried about its role in unnecessary “productivity.” The great increase in journals now “born online” (most are OA), has meant publishing opportunities that did not exist two decades ago. Many are worthwhile—there is always room for new ways to represent knowledge. But the journals and articles are piling up and it is hard to believe that it is all necessary—apart from the professional needs of authors. And, alas, the problem of “predatory publishing,” or the schemes of spurious journals to gain APCs from inexperienced authors, can add to skepticism about OA although the DOAJ itself claims that the problem is not as extensive as some assert (Beall, 2012; Olijhoek and Tennant, 2018).

By a decade into this century there were expressions of dismay about the publishing “avalanche” or “glut” and what it signified. “While brilliant and progressive research continues apace here and there,” academic observers say, “the amount of redundant, inconsequential, and outright poor research has swelled in recent decades” (Bauerlein et al., 2010). The best evidence for that, these critics note, is that fewer than half of the scientific articles published are cited even once. Thus, productivity may be high, defined as the number of articles published, but impact and utility are low. Indeed, the “productivity climate” has this effect according to literary studies and education scholar Mark Bauerlein and his co-authors: “Aspiring researchers are turned into publish-or-perish entrepreneurs, often becoming more or less cynical about the higher ideals of the pursuit of knowledge.” There are consequences for people and for budgets, whatever the low cost of digital and OA publishing: “We need to understand that there is such a thing as over publication, and that pushing thousands of researchers to issue mediocre, forgettable arguments and findings is a terrible misuse of human, as well fiscal, capital.”

There are legitimate questions about what peer review now means in a time of mega journals, the pressures on finding qualified and willing reviewers, and the steady growth of preprint servers and repositories. Can an article that appears only on preprint server count as “published”? Likely not for most tenure and promotion communities. But for many contributors to arXiv appearing there is enough, with the next steps in the formal journal based publication process unnecessary. Indeed, a report from the International Science Council finds in “The Normalization of Preprints” a sign of recognition that conventional peer review no longer carries primary authority in establishing research legitimacy (Drury, 2022). The preprint represents the advantages of the digital system to authors and readers alike, and to the benefits of timely uses of research. According to the ISC universities should adapt the academic reward system to acknowledge the change and new habits of inquiry. With work from a reputable OA source already in the hands (or on the screens) of readers months or even years before it would have reached them in a traditional journal it is time to go on to the next article. Of course many scientists and scholars still prefer the traditional system, from habit or the belief that it contributes to the rigor and durability of research, and to any case made for career advancement.

The sizable annual increases in the number of scientific and scholarly articles appearing in formats of all kinds can obscure questions being asked about research and publishing itself. Thus, an account of the rate of publishing in sociology makes plain that the decline in opportunities for tenure track faculty work has meant extraordinary pressure on young scholars to publish as much (and as quickly) as possible (Warren, 2019). Has the result been a period of exceptional research productivity or does it simply represent a “bubble” or “glut” reflecting the new professional conditions of academic work including the proliferation of OA journals? (Trimble et al., 2010; Génova et al., 2016).

Philosopher of education Nicholas Burbules asked in 2020 if scholars and institutions have been neglectful and even complacent about what has happened in recent decades. He recognizes the several good reasons to write and publish, including extending human knowledge, communicating with colleagues, and even fortifying individual identities as scientists and scholars. But the effects of the “publishing treadmill” should prompt serious rethinking about the system, including what Open Access has contributed to the “explosive availability of online publishing opportunities” (p. 662). The combination of the incentive system for authors and publishers alike, if reflecting different motives, and the digital reorganization of publishing opportunities, have left us with more and more unread work. As decentralized and complicated as scientific and scholarly publishing is, however, with what the OA movement has added to it, Burbules finds it hard to see beyond academic humility as a way to slow or stop the treadmill. Of course, as Burbules acknowledges, new habits of academic self-promotion via social media are driving things in the opposite direction, reflecting the overcrowded digital marketplace. More modesty, including self-imposed limits on publishing are what chemist David Muddiman (2016) believes will yield higher quality work and more satisfying careers. The goal would be to abandon the current habit of seeking a place for the “minimal publishable unit” (the MPU) and focusing instead on the “highest publishable unit” (HPU).

For historian of education David Labaree (2018) no external rationale is necessary for explaining the expansion of academic publishing in our time. It is an essential feature of faculty work. In a recent account of it he acknowledges that in a surplus of writing only a small number of articles are “worth reading” or “make a substantive contribution to their field.” And Labaree says that “It’s sad to see academic scholarship fall into a state where the accumulation of lines on a CV matters more than producing quality work.” He appears to agree with Altbach and De Wit. But no, according to this speculative formula: “Maybe it’s worth tolerating a high level of dross in the effort to produce scholarly gold.” Thus, for Labaree and seemingly most scientists and scholars the “incentive system for faculty publication still provides net benefits for both the academy and society.”

To the degree that the OA movement, with its intellectual and social idealism, has had a role in the steady growth of publishing, it is now part of a system increasingly accountable for its seemingly limitless expansion. Paradoxical as it may sound, looking ahead in 2006 Willinsky proposed that OA advocates have roles in skepticism about the looming outburst in journal publishing. "This overstated critique only raises the need for a more fundamental calling to account of higher education" (p. 137). For some scholars that is what is happening. Indeed, recent arguments for more "public engagement" by scientists and scholars, including seeking out OA opportunities, reflects disappointment with the conventional academic preoccupation with publishing as primarily a resource for professional advancement (Hoffman, 2021). And such arguments remind us that access should mean more than availability. As audiences expand, in adjacent disciplines and among non-academic readers, scientists and scholars can strive to be understood in ways that educate without excessive specialization. In effect, OA can reflect a form of academic "generosity," academic writing being an invitation to learning for all as well as a medium of professional knowledge making (Fitzpatrick, 2019).

Conclusion: the "shock of the new," again and again

A decade after the Budapest Declaration its author acknowledged that the changes in scholarly communications it urged had steadily gained ground. Open Access could be seen as "a solution to serious problems." But there was still "the need for the sheer passage of time to overcome the shock of the new" (Suber, 2012, p. 167). The example of arXiv had set the stage for OA principles. In the 1990s the preprint offered an alternative image of publishing. It is still thriving, with allied innovations in OA (Drury, 2022). Indeed, the COVID-19 crisis demonstrated how a purposeful if informal global alliance (or "scientific globalism") could demonstrate the virtues of OA in a scientific emergency (Horbach, 2020; Lee and Haupt, 2021).

Still, a new development, the so-called "transformative agreements" between the publishing oligarchs and major academic libraries, can prompt the view, among competing ones, that the lessons of OA are all about business models and sustaining the traditional system (Hinchliffe, 2020; Pool, 2021). But for the Organization for Economic Co-operation and Development's Toby Green (2019), troubled as he is by the success of Sci-Hub, the notorious outlaw dissemination service (Bohannon, 2016), OA will never solve the problems of cost, at least in the Gold version many academic authors accept. What is needed is the "transformation" (as Green uses the term) of the entire system of scholarly communication. Pre-prints and repositories would have primary roles and major journals maintained only to showcase a very small percentage of the best work. "Subscribe to Open," launched in 2019, is another OA experiment now underway but initial results are hardly transformational. By 2021 it had not gained participation from any of the major corporate publishers (subscribetoopencommunity.org; see also Harrington, 2021).

"Transformation," as in the title of this chapter, can have yet another meaning. The OED specifies "changes in form, shape, or appearance." For an influential group of scholars of journals in the decades ahead there will be new rounds of the "shock of the new," as experience and technology reveal fresh ways to design and present research (Herman et al., 2020). From text enhanced with media, to the megajournal, to the uses of "plain language" summaries, to new forms of social media based professional communications, to public formats for peer review, and more, authors and readers will encounter many tests of their scientific and scholarly habits. But so too will they face organizational reforms also intended to be transformational. Technological change in higher education, as in other domains, is often initiated with such a claim (e.g., Floridi, 2014).

Communications reflects the goals and activities of authors, from the publishing formats we know, to those we are experimenting with, to the unknown innovations that lie ahead, all aimed at establishing and maintaining relations with others dedicated to inquiry, colleagues and students alike. These are, as Suber and Willinsky insist, activities that should now be guided by "open" as the principle animating faculty work. Designating OA as an "unfinished" transformational project means that it is necessary to view it against its original goals, questions of scholarly communications it directs us to, and the evolving conditions of knowledge dissemination. But we can likely count on the continuing withdrawal of paywalls for science and scholarship as higher education welcomes new expressive opportunities.

Introduction

The quality of university student learning is an ongoing concern for those leading universities, for students, teachers and parents alike. Innovations in pedagogy, changes in the remit of universities to widen access and advances in Internet and computer-based technologies have increased the growth of alternative configurations of university credentials, structures of the student learning experience and even the learning spaces themselves, creating an urgent need for entirely new ways of conceptualizing and assessing the learning experience of students (Ellis and Goodyear, 2019; Wong et al., 2019). Research has repeatedly found positive impacts of various forms of innovations in learning, such as learning embedded in groupwork, inquiry-based learning, problem-based learning, social networking sites, web-conferencing for peer learning, e-portfolios, virtual spaces and second worlds (e.g., Anderson, 2016; Ngan et al., 2018). The higher education sector's rapid development in the use of computer and web-based technologies has motivated and shaped innovations in the experiences of learning of university students worldwide. These developments have created significant theoretical, methodological and philosophical challenges for researchers and those concerned about the quality of learning experiences at university. How do you evaluate the innovations and the quality of learning when part of the experience is in class and part is online? What role do learning technologies have in a quality learning experience? How do students collaborate in blended learning contexts? How should teachers design courses which require students to go back and forth between in-class and online contexts as they pursue their learning outcomes?

The challenge

This chapter considers these questions in the context of 50 years of research into university student learning, most commonly referred to as Student Approaches to Learning (SAL) (Pintrich, 2004; Prosser and Trigwell, 1999; Trigwell and Prosser, 2020). SAL is a relational model of the student experience of learning in which student prior characteristics of learning, the learning environment of their course and the perceptions the students hold about it, their approaches to, and conceptions of, learning and learning outcomes are inextricably entwined and contribute in different ways to the quality of the experience. Fig. 1 provides a visual presentation of the model.

SAL has been an important research program into the quality of university student learning. It has clarified the relationality of key aspects of the university student learning experience and how those aspects are related to each other in the context of qualitatively different outcomes. In summary, deep approaches to learning are related to positive perceptions of the learning context, cohesive conceptions of learning and relatively higher academic outcomes. In contrast, and significantly, surface approaches to learning are related to negative perceptions of the learning context, fragmented conceptions of the learning and relatively lower academic outcomes. It is the relationality amongst these aspects that allow institutional leaders, teachers and students to improve learning outcomes. An adjustment in how a student perceives the learning context can lead to deeper approaches to learning. A clarification of the concept of the object of learning in an experience can lead to a better perception of factors that shape the quality of learning outcomes. Five decades of research suggest that these qualitative shifts can lead to relatively higher academic outcomes for students.

Fig. 1 The student experience of learning (3P model). Adapted from Prosser and Trigwell (1999).

While SAL has much to offer in understanding contemporary university student experiences of learning, it was not designed to deal with observational forms of evidence such as how students use learning technologies, nor with measurements of student group and teamwork. Understanding variation in conceptions, approaches and perceptions of learning has been shown to be essential if we want to understand variation in the students' ability to achieve learning outcomes. However, these self-report variations do not reveal granular descriptions of different strategies when hundreds or thousands of students use learning technologies in tens of thousands of different ways and sequences. To understand how material elements in the university student experience of learning are related to conceptions, approaches and perceptions of learning, it is illuminating to consider where they might be located in the 3P model of the learning experience in Fig. 1.

When looking at Fig. 1, it is possible to imagine how material elements might be conceived of in the course and departmental context, and how a student's use of technologies might be in approaches to learning and consequently in their perceptions of learning technologies in the course (Ellis and Bliuc, 2019). However, there are many additional challenges in studying the complexity of experiences of blended course designs (Ma and Lee, 2021), including students' choices of social interactions in learning, such as with whom and how to collaborate (Claros et al., 2015); and the purposes for which they use learning technologies in both physical and virtual learning spaces (Ellis and Goodyear, 2013; Laurillard, 2002). As such, it is valuable to evaluate university student learning experiences of blended course designs with research methods that move beyond self-report data to include observational data. By combining different sources of data and appropriate accompanying methodologies, researchers are able to develop a more holistic understanding of the contributions of learners and material things involved in learning to qualitatively different levels of academic performance, (Ellis and Goodyear, 2013; López-Pérez et al., 2011; Wu et al., 2010). To understand how observational evidence can elaborate the value of self-report evidence of student learning, the following begins with SAL methodologies and the insights it provides, and then considers methodologies that draw on observational and self-report data offering complementary yet alternate perspectives on qualitatively different outcomes.

Research into student approaches to learning

Early seminal SAL studies described variation in student approaches to studying (Marton and Säljö, 1976; Svensson, 1977). Approaches to studying were found to largely fall into one of two categories: deep approaches, which were closely related to understanding, to reflective and evidence-based thinking; or surface approaches, which were more mechanistic in nature, tending to simply reproduce without seeking the underlying meaning of the activity or outcome. These associations were found in student approaches to studying and examination performance (Svensson, 1977) and in student approaches to studying and the way they read passages. The latter study designed the questions for three separate reading tasks and discovered that the design of the questions about the readings if poorly designed, were more likely to induce a surface approach to studying.

Key contributions of SAL have been the identification of qualitatively different variables of approaches to learning and conceptions of learning, adopted by multiple well-cited researchers in the field (Biggs, 1987; Biggs and Tang, 2011; Entwistle and Tait, 1990; Prosser and Trigwell, 1999; Trigwell and Prosser, 2020; Ramsden, 1991, 2003). The following provides some examples of qualitatively different experiences of learning through discussions in a Social Work course (Ellis, Goodyear, Prosser, & O'Hara, 2006).

The examples in Table 1 present fundamental differences in the ways students conceived of learning through their discussions in a course that graded discussions in class and online as part of the assessment framework. The most holistic conceptions of

Table 1 Qualitatively different examples of conceptions of learning through discussions.

Category	Description	Representative quotation
A Challenging ideas	Discussions as a way of challenging ideas and beliefs in order to arrive at a more complete understanding	It (discussing) challenges my beliefs, which is always good ... because a belief is something that is based on knowledge and experience and your understanding of the world, and if it is being challenged you are testing it ... If my beliefs are challenged, I believe that my understanding of concepts is more complete
D Checking ideas	Discussions as a way of collecting ideas	Getting the teacher's point of view ... it's good being able to talk and make sure you are really learning what you are supposed to be learning. It is just sort of reassuring

Adapted from Ellis et al. (2006).

discussions reported that discussions were a way of testing one's beliefs and understanding. The accompanying interviews showed that it was the very process of challenging ideas through iterative conversation back and forth that clarified misconceptions and confirmed facts and evidence upon which beliefs were built. In contrast, some conceptions of discussions were focused on formulaic and mechanistic strategies that emphasized reproducing the ideas of the teacher, rather than developing personal understanding. In these conceptions, students thought that if they could reproduce the teacher's ideas, then they would be confident and succeed.

In the same study, students reported qualitatively different approaches to learning through discussions.

Table 2 describes qualitatively different approaches to learning through discussions in the same course as the conceptions in **Table 1**. The first thing to notice is that while a conception of learning through discussions encompasses both those in class and those online, the description of an approach to learning through discussions is described separately in order to reveal the intent and strategies adopted in class and those strategies adopted online. This is because not all strategies that work in class will necessarily suit an online context and vice versa. Deep approaches to learning through discussions in class emphasize comparison between one's own ideas and the others heard in discussions and use them as a way to receive feedback on ideas. Online, deep approaches emphasize reflection enabled in part because the exchanges are often asynchronous, with plenty of time to think in between posts. Significant reflection often involves considerations of how to apply the ideas on which are being reflected. In contrast, students reporting surface approaches to discussion do not approach them as a way of learning, but rather as a way of being exposed to different ideas so you can string them together. When pressed, discussions seem to be about fulfilling task requirements. This includes discussions online which may involve strategies of reading other postings in order to get a good mark or avoid repetition.

Quantitative approaches to identifying qualitative variation in learning

SAL has a long history of using quantitative methodologies in order to investigate and distinguish between the quality of the learning experiences of groups of students in the same class. Key instruments used in the research area are Biggs Study Process Questionnaire (Biggs, 1987; Biggs et al., 2001), Entwistle's Approaches to Study Inventory (Entwistle et al., 2000), Ramsden's perceptions subscales (Ramsden, 1991), Trigwell and Prosser's teaching inventory (Trigwell and Prosser, 2004).

As an example informed by these approaches, one study looked at engineering students' approaches to learning through discussions in an undergraduate class. In the final phase of the study, quantitative scales identified the following qualitatively different groups using cluster analysis.

In a third-year undergraduate engineering course, students were studying how to set up an e-commerce business. As part of their assessment, they were graded on their discussions in their laboratory work and online fora in relation to how well they demonstrated an understanding of the stages of setting up a business. The cluster analysis in **Table 3** identified two groups of students: one group who recorded high scores on fragmented conceptions, surface face-to-face and online approaches with low scores on cohesive conceptions, deep face-to-face approaches, and course marks. In contrast, the second group recorded relatively high scores on cohesive conceptions, deep face-to-face approaches and course marks and low scores on fragmented conceptions, surface face-to-face and online approaches and course marks.

These results provide outcomes consistent with the 3P model and previous research in the area. The results show the difficulties teachers face in achieving alignment with the learning outcomes of a course, particularly when including online parts into course design which require students to pursue their learning outcomes back and forth between in-class and online contexts. The results indicate the persistence of difficulties in helping students to adopt deeper approaches to learning and relatively more cohesive conceptions of learning and have been replicated and developed further across tens of thousands of students in many different universities on multiple continents (Biggs and Tang, 2011; Ellis and Goodyear, 2013; Prosser and Trigwell, 1999; Ramsden, 2003; Richardson, 2000).

The studies reported above and others in the SAL field have highlighted key challenges in ensuring the quality of the university student experience of learning. The evidence from the self-reported studies by students suggest that not all students experience the course design in the same way; some have misconceptions about what they should be learning, others have poor approaches to their learning both in class and online. Others report clear conceptions of the purpose of the course and learning outcomes; and useful,

Table 2 Qualitatively different examples of approaches to learning through discussions.

Category	Description	Representative quotation
A	Engaging in face-to-face discussions to analyze experiences and opinions through feedback	<i>Face-to-face</i> As far as learning, I like other people's ideas. I am never presumptuous enough to think that anything I say is the absolute truth and um for all I know I could be completely wrong ... I like to see how other people absorb my information. It is important to me that I have explained it well enough so other people can learn off it. I have always thought that if you can explain something to someone else, for example my girlfriend is in Year 12 right now and I really didn't do well in chemistry and after tutoring her I am like I could do my HSC now. To me it is important that I can explain my ideas so it is good to be able to let other people in and plus I get their feedback on it as well immediately.
	Engaging in online discussions to evaluate postings to reflect on key ideas	<i>Online</i> It just makes me think, like the ideas, like someone today when a post I made this morning and one two days ago, which was about men in counseling and about how they just feel society pretty much pushed them out of it. It wasn't really that original but it was something which I hadn't thought of before. So I mean, I didn't respond to it because I didn't have much to say. It was just something for me to think about it as I come to University, and it will be something that I have already thought about and probably be able to apply it.
D	Engaging in face-to-face discussions to fulfill task requirements	<i>Face-to-face</i> I don't think there is that much learning, the most amount of learning would happen in lectures... I don't think there is that much learning, I think it's just embracing different ideas and I don't think you are actually learning something, I think what's in the readings it's not what you actually learn it's just stringing them all together and engaging, yeah.
	Engaging in online discussions to read postings to avoid repetition	<i>Online</i> I tend to read all of them first. Because I tend to want to write something a bit different from all of them and sort of stand out a little bit because I thought I would get good marks for that, but that's not the point. But then if I read all of them as well I can reply to some of them, that's the thing like if I agree with someone's posting, then I can reply which is always good and then extend on from what they have just said. So yeah I tend to read all of them first yeah.

illuminative and deep approaches to learning. Furthermore, a key significance of these findings is the relatedness of key variables, such as conceptions and approaches to the quality of outcomes. It seems that teachers who succeed in helping students to move from surface approaches to deeper approaches, will also encourage students to develop more holistic and meaningful conceptions of what they are learning. Similarly, if they are able to clarify the purpose and goal of what the students should be learning in ways that help students to move away from fragmented conceptions toward cohesive ones, then the research suggests that students are more likely to adopt deeper approaches to their learning.

The outcomes from SAL research have a strength in that they use both qualitative and quantitative methodologies in order to reveal the qualitative variation across the student experience of learning. A combination of methodologies helps to provide a more thorough understanding of the student experience and offers actionable knowledge to teachers and education leaders who seek evidence upon which to design the program profile of a university. However, SAL research has been criticized for its reliance on self-report data including interviews only. There is an opportunity in higher education research to make use of the increasing availability of observational data from learning technologies in the form of learning analytics. For this reason, we discuss how a use of observational data in research designs into learning can complement, extend and enhance our understanding of the qualitative variation in the student experience.

Materiality data used to complement self-report data as evidence of learning

To understand how an evaluation of materiality in the student experience of learning can help improve student learning research and the actionable knowledge it provides, it is valuable to consider the role of materiality in learning, including the observational evidence it can offer to improve learning and the suggested pathways for research its combination with self-report data offers the field in the decades ahead. The examples described in the following capture methodological developments in research into university student learning from a series of closely related investigations by the authors and colleagues.

Materiality in the university student experience of learning is most ubiquitously understood in terms of the learning technologies that most students are using in contemporary course designs. It can also apply to other material aspects of the student experience such as learning spaces, but for the purposes of this chapter we use learning technologies as an example. A crucial concept in considering how learning technologies may be investigated for their role in contributing to qualitative variation in the learning experience is “entanglement”.

Entanglement

The idea of entanglement helps to conceptualize how non-human elements are bound up within university student learning processes (Fenwick, 2012). Contemporary course designs in university programs typically involve learning technologies in activities such as communication, research, reading and writing. In any activity it is common for a student to use a tool to support a process of, for example, writing, skim-reading, listening, talking, thinking, simulating or searching. Usually technology-enabled processes are an integrative and iterative experience as the student traverses back and forth and hopefully integrates ideas across resources, technologies, physical and virtual spaces and discussions. In practice it is difficult to know where one part of the process ends and another begins as the student engages in integrated processes that help them move toward their learning outcomes. It is in this sense that material aspects of the learning environment become entangled within the processes of the student experience of learning.

This idea of entanglement is very helpful to researchers seeking to understand how hundreds if not thousands of students might use learning technologies in their university experiences. Machine learning, algorithms, structural equation modeling, cluster analyses and other techniques can be used for descriptive, diagnostic, predictive purposes on large sets of observational data from the digital traces left behind by students engaging with the learning technologies, particularly online and networked tools and platforms. When these research methods draw on observational data, they can be used to complement and strengthen the findings of self-report data sources drawn from the same learning experiences. By providing outcomes from methodologies using both self-report and observational data, the understanding and usefulness of the knowledge arising from the research studies is likely to be more holistic and actionable.

The outcome of these methodologies involving large datasets are insights about the patterns of learning that can be discerned. While these are potentially very valuable, the area of learning analytics has received criticism that it does not frame the methods sufficiently in theory and that a lack of context of the intent behind the students’ use of the tools means that the interpretation of the results may be indeterminate at best and erroneous at worst (Boyd and Crawford, 2012; Selwyn, 2019). The combination of observational data sources with self-report data and methods helps to address this criticism, particularly if the self-report data emphasizes the theoretical context and intent of the learners. The self-report data described in the first part of this chapter for example, incorporates a use of extended interviews, carefully transcribed and analyzed and used to develop quantitative instruments within the SAL framework that can survey larger population samples. The point made here is that this type of self-report methodology, along with observational data and methods drawn on from within the same theoretical framework will provide relatively more holistic and complementary evidence about the qualitative differentiation of student experiences of learning. We are not suggesting that any one particular method is better than another, but rather a carefully designed and complementary use of self-report and observational data and methodologies will help provide knowledge which offers more insight into the actions that may lead to

improved experiences of learning. The benefits of combining self-report and observational sources of data are not, however, just limited to relatively more holistic research outcomes. They might also help us to discover how particular configurations of students, activity designs and technologies might enable a greater understanding by the way these elements combine, something that can be referred to as “emergence”.

Emergence

In addition to providing more useful results about learning involving materiality, the idea of “emergence” will help those concerned with the quality of university student learning not to miss any potential advantages for learning outcomes that may arise when non-human elements are part of the design of the learning experience. The idea of emergence probably first came from philosophical writing of Lewes ([Lewes, 1877](#)) who distinguished between resultant effects and emergent effects. The former can be measured simply by adding or subtracting the causes of the effects. In contrast, emergent effects are qualitatively more than the sum of the parts that led to the effects.

In the area of meteorology, a vortex is an example of emergence. Broken down to simple elements, a vortex may be made up of sticks, soil, stones, wind and other matter. However, when combined in a certain way, tornados and hurricanes create their own energy. In learning, there is potential for combinations of human and non-human elements like learning technologies to add to the understanding of students if they are used in certain ways in designs by teachers who understand how to help students develop deep approaches, cohesive conceptions and positive perceptions of their learning experience. In order to investigate this potential, research methodologies and the designs of research projects need to move beyond just looking at individuals as the unit of research, but individuals plus the non-human elements they use as they seek an outcome. The challenge in combining the unit of research to include both human and non-human elements is to identify appropriate self-report and observational data sources which are related and complementary.

Entanglement in the 3P model

We saw in the first part of the chapter that students adopt approaches to learning through discussions whose strategies are distinct to those they may adopt in class, some more effective than others. So it is clear that entanglement can occur in approaches to learning. Another fruitful area for understanding qualitative variation in the student experience of learning that arises from entanglement is their perceptions of the learning environment ([Han and Ellis, 2020a](#); [Ramsden, 1991](#)). The relationality of the 3P model suggests that students with positive perceptions of their experience, such as their perceptions about the quality of teaching, the clarity of the goals and standards of the course, the appropriateness of the assessment and overall satisfaction, tend to approach their learning in deep ways, hold cohesive conceptions and perform academically higher. Those with negative perceptions of these elements tend to adopt surface approaches, hold fragmented conceptions and tend to perform academically lower.

The relationality of perceptions to the quality of *material* affordances of their learning environment to the quality of outcomes has shown consistent associations across a number of emerging studies ([Ellis, 2016](#); [Han and Ellis, 2020b](#)). [Table 4](#) presents some example items investigating student perceptions of how the online part of their experience is related to their whole course experience.

Recent research has identified that students’ perceptions of a number of interesting aspects of their online experience are logically and positively associated with the quality of their learning outcomes ([Han and Ellis, 2020b](#)). These include how well integrated the online part of their experience is within their whole course design, their perceptions of the value of the online contributions from other students and their perceptions of the workload online in relation to the whole workload for the course. In short, students who adopt deep approaches to learning in blended course designs, tend to hold positive perceptions about these aspects and tend to perform relatively academically higher than those who hold negative perceptions of these aspects. So when considering approaches to online discussions from earlier in the chapter, and perceptions of the online part of their course experience, it is possible to see how entanglement can be conceived as a key dimension of the students’ whole experience of learning. However, these observations are built around self-report data sources and methodologies. How do we consider materiality in the learning experience methodologically using observational data? The next section considers this question with some examples.

Combining self-report and observational data in investigations into blended course designs

To improve the insight from research into student experience of learning in blended course designs, a combined use of self-report and observational data that includes dimensions of the materiality of the experiences has the potential to offer elaborated and relatively more holistic results to inform the actionable knowledge discovered from the research. As an example, the following summarizes the outcomes from a study into a first-year undergraduate engineering degree ([Ellis et al., 2017](#)). Students were expected to design an electronic system to solve an engineering problem, demonstrate how it related to the theoretical framework of the course, including basic programming constructs, write a report on the process and results and engage in a team-based process, which made significant use of the online environment. In the online environment, they were required to interact with the subject matter of the

Table 4 Perception subscales of key aspects of online environments in university courses.

<i>Subscale</i>	<i>Item</i>
Perceptions of integration between face-to-face and online	The online activities helped me to understand the lectures in my course. The online activities seemed to be well integrated with the assessment. The resources on the course website helped me to understand ideas in class. Studying online materials helped with the assessment in the course. I found the resources on the course website very useful for my learning.
Perceptions of online contributions	The ideas online in this course related to the ideas in class. Other students' online contributions helped me understand my ideas from a new perspective. Online contributions from others prompted me to reflect more on the ideas in this course. Online contributions from other students helped develop my understanding of particular topics. Online contributions by students in this course motivated me to think about things more. Online contributions by students in this course prompted me to engage more.
Perceptions of online workload	I needed more time to do my online activities. By the time I finished the online activities, I was running behind. The online learning in this course took too much time. The workload for the online activities was too heavy. A better balance between the online activities and the other tasks would help my workload.

Adapted from Han and Ellis (2020b).

course and engineering problem, engage with the online videos and multiple-choice questions, interact with the formative assessment elements and submit them and use feedback about their participation to gauge the level of their effort.

In that study, the approach subscales used were from the revised Study Process Questionnaire (Biggs et al., 2001). These were the self-report variables. The observational variables were the frequency of use of the online tools that enabled the students to engage with the resources, videos, multiple-choice questions, and feedback information from the dashboard. Table 5 presents the two-cluster solution of the experience. All variables were statistically significant in this study except for time spent online (duration).

Table 5 presents two qualitatively different groupings of students in the engineering course. One group of 43 students, who reported positive, statistically significant scores on the deep approaches to study variable, all the observational variables and the academic performance variable as indicated by the course mark. In contrast, a second group of 102 students reported a positive statistically significant score on the surface approaches to study variable, and negative scores on all the observational variables and a negative score on the academic performance variables as measured by the course mark. In brief, students reporting a deep approach to study, objectively and relatively engaged more with the online environment in statistically significant ways and performed a relatively higher level of academic achievement; whereas students reporting a surface approach to study, objectively and relatively engaged less with the online environment and performed at a relatively lower level of academic achievement.

Another aim of the above-mentioned study (Ellis et al., 2017) was to examine what contributions the observational variables made to the research design and results. To achieve this aim, two multiple regression analyses were performed. The first model involved the self-report variables only and the second model includes both the self-report and observational variables. Table 6 presents the results of the regression analysis. The self-report variable that was significant (surface approach to study) accounted for 9% of the variance in the outcomes. When the regression comprised both the self-report and observational variables, the model was able to explain 34% of the variance.

These results have been replicated with various levels of additional variance explained in Model 2 in a number of studies (Han et al., 2020; Pardo et al., 2017). Some of the designs of those studies have adopted machine learning methodologies to deal with data at scale. The innovation in the research methodology being emphasized here is the value of including observational data variables to complement and extend the results of the self-report variables within the same theoretical framework. By combining the data sources in the research design, the depth of insight into reasons for the variation is relatively more detailed and offers relatively more evidence for the development of actionable knowledge.

Table 5 Summary statistics of the two-cluster solution of the engineering student experience.

Variables	Deep cluster (n = 43) Mean (SD)	Surface cluster (n = 102) Mean (SD)	F	p	η^2

Conclusions

The contemporary context of university student learning is characterized by an unprecedented amount of change. These changes are occurring in the areas of credential design, pedagogical approaches, learning technologies, and activity design. To understand the impact of these changes on the quality of the student experience of learning; robust, valid and reliable data is required from different perspectives on the experience so that findings can be extended, elaborated and enhanced. This can be achieved if self-report data is combined with observational data from the same learning experience and investigated within a strong theoretical framework like the SAL framework.

A key challenge in investigating university student learning in contemporary contexts is how to appropriately account for the contribution of materiality in the experience. Within the SAL framework, the ideas of entanglement and emergence help to conceptualize an integrated and embedded use of learning technologies that is consistent with the real-world use of learning technologies by students in their learning. Some students do adopt relatively deep approaches to learning, including when they use the technologies, and these tend to be related to cohesive conceptions about their subject matter, positive perceptions of the blended learning environment and relatively higher academic outcomes. Similarly and in contrast, other students adopt relatively surface approaches to learning, which are related to ideas about the subject matter which do not quite get the whole picture, but miss key aspects of what is being studied. These experiences tend to be related to negative perceptions of the learning environment and relatively lower academic outcomes.

The university student experience of learning is likely to continue to face ongoing change in the context in which it is occurring over the next decade. Consequently, those responsible for learning in universities, including the program directors, course convenors, teachers and even the students themselves, will benefit from evidence that provides real-work actionable knowledge to improve how, what, why and where students learn successfully.

Introduction

Pandemics are known as worldwide epidemics of excessive number of sicknesses that cause deaths, social disruption, high inflation and economic downturn (Nicola et al., 2020; Karabulut et al., 2020; Piret and Boivin, 2021). Over the years, there has been recorded history of pandemics in human history (Huremović, 2019; Karabulut et al., 2020; Piret and Boivin, 2021). Some of such historical pandemics include: the Spanish flu in 1918–1920, which was the first global pandemic, Asian flu in 1957, Hong Kong flu in 1968 and swine flu in 2009; the smallpox outbreak in the former Yugoslavia in 1972, HIV/AIDs which started in the United States of America in 1980s, Ebola outbreak of 2014–2016 that ravaged mostly the Central and West Africa (Huremović, 2019; Akin and Gözel, 2020; Bai et al., 2020; Lyngdoh, 2020; Owusu-Fordjour et al., 2020; Zhai and Du, 2020).

This chapter will focus on the most recent COVID-19 pandemic by providing an analysis of the uses of technology in navigating the pandemic in selected African countries.

The report of the outbreak of the novel COVID-19 in China at the end of December 2019 took the world by surprise. What started as a potentially dangerous but yet less seriously taken outbreak evolved to become one of the most important global occurrences of the 21st century with such devastating effects. Within a period of 4 months the virus had mutated from an epidemic to a pandemic that had engulfed the whole world. By mid-April UNESCO (2020) reported that 192 countries had closed all schools and universities, affecting more than 90% of the world's learners: almost 1.6 billion children and young people. With the massive closures of all education institutions, societies had to deal with unprecedented disruptions of teaching and learning in schools, colleges and universities which many sectors of society were unprepared for. The pandemic further triggered the closure of borders and restricted human travel to all, regardless of social, political or economic class, and it in this way became the "greater equalizer" in the midst of an unequal world (Emeto et al., 2021; Memish et al., 2021).

The pandemic further impacted the economies of many countries especially in Africa leading to the shrinking of their revenue bases (Gondwe, 2020; Obayelu et al., 2020). This forced the redistribution of and reprioritization of the use of meagre resources to more urgent needs and sectors, such as agriculture, food security and COVID-19-related healthcare. In some cases, the reprioritization process led to the postponement or even cancelling of commitments, for instance, to capital development, research and innovation and hiring staff, among others. Furthermore, societal lockdowns and spending to combat COVID-19 led to substantial and increasing economic challenges (Mhlanga and Ndhlovu, 2020). These may have an even greater impact in low- and middle-income countries. This happened in a context where many African countries were already dealing with issues of declining funding in real terms, government regulation of tuition fees, rising student debt, weak economic growth and weakening and volatile currencies.

Literature on COVID-19 focuses on the challenges and opportunities associated with online learning during COVID-19 (Ade-doyin and Soykan, 2020), the global impact of this pandemic on social, economic and health sectors of society (Ciotti et al., 2020; Adedoyin and Soykan, 2020; Daniel, 2020; Pokhrel and Chhetri, 2021). A study of COVID-19 pandemic in Africa by Lone and Ahmad (2020), focused on the vulnerability, preparedness and economic impact of COVID-19 in the African continent. There have not been enough studies that focused on the uses of technology in African higher education institutions in navigating the pandemic.

The purpose of this chapter is to discuss and analyze the challenges and implications of COVID-19 for higher education in Africa and the opportunities that arise therefrom. It will argue that while the COVID pandemic has accentuated the inequalities between African higher education systems and the rest of the world, it has also provided opportunities for innovation that may inform policy for the delivery of quality higher education.

Many education systems on the African continent, just like the rest of the world were, unprepared to deal with the pandemic. This calls for national governments to invest in their education systems to be robust and resilient throughout the 12 years of basic education, and for the higher education system to be agile in dealing with such disruptions. The unequal access to technological devices, data networks and reliable electricity supply impacted not only schools and universities but also the preparedness of educators, parents and the learners themselves to move rapidly to remote teaching and learning. These also revealed the glaring differences between rich and poor communities and nations. COVID-19 put on a mirror in front of many societies of the world to see and realize both their strengths and resilience on the one hand but also exposed the vulnerabilities of weaker communities especially in developing countries, on the other.

The closure of educational institutions across 165 countries, which affected 1.5 billion learners forced higher education institutions to think of new ways of ensuring learning continuity outside the four walls of the classroom. Since the outbreak of the Covid-19 pandemic, several studies (Hodges et al., 2020; El Said, 2021; Le Grange, 2020; Heyang and Martin, 2021; Menon and Motala, 2021; Ngwacho, 2020) have been conducted to explore how higher institutions around the world navigated through the unprecedented change in traditional teaching and learning. The most popular response to the crisis was a move to online delivery of lessons on diverse digital platforms United Nations (2020); even though early indications had suggested that online instruction was a poor substitute for face-to-face instruction (Domina et al., 2021). According to Bond et al. (2020), good number of higher education institutions (HEIs) adopted what was termed the “Emergency Remote Teaching—ERT” to mitigate the effect of the pandemic on education delivery. However, Hodges et al. (2020) and Le Grange (2020) argued that a shift to online teaching and learning in response to a crisis is not as authentic and as meaningful as a well-thought-out plan, as a sudden shift could be shocking to academics and students. Hodges et al. (2020) further argue that an ideal time to plan, prepare and develop a full university online course is between six to nine months and so, it would be impossible for lecturers to suddenly become experts in online teaching in a time of crisis or disaster. That notwithstanding, the timely effort of some African countries and HEIs in responding to the pandemic, mitigating its adverse effects on education and promptly leveraging technology for remote learning is laudable. The emergency remote teaching was implemented with various levels of success in many African countries. The following sections examine how some African countries and HEIs used technology to mitigate the effects of the pandemic to ensure continuous education delivery. In order to get a sense of how of the pandemic was dealt with and responded to by African higher education institutions, a selection of four countries representing the four major regions of the continent namely the North (Egypt), South (South Africa), East (Kenya) and West (Nigeria) was conducted to examine the use of technology in mitigating the effects of the pandemic. Additional cases of other African countries drawn from recent literature were also analyzed to provide more insights on how some of the countries used technology to navigate the pandemic.

Egypt

Egypt has the largest education system in the Middle East as well as North Africa with 44 universities and 830 other higher education institutions, enrolling 3 million students (El Said, 2021). As in other African countries, the Egyptian government made a swift move to close down all education institutions at the onset of the pandemic in March 2020. To ensure the continuation of educational processes, the Egyptian Ministry of Higher Education and Scientific Research urged all higher education institutions to adopt the modality of distance education under lockdown (El Said, 2021). Online platforms were then set up, in cooperation with Microsoft International and Blue Cloud for Software Development, (World University News). The platform allowed both faculty members and students to apply social distancing measures to combat the spread of the novel coronavirus (COVID-19), as well as allow for easy communication during virtual classes.

To measure the satisfaction of higher education stakeholders on the distance education mode, El Said (2021) reported that four-nation wide surveys were administered to students, education leaders, professors, and administrators in May 2020. A total of 106,897 participants completed the survey; and the findings showed internet connectivity and weak IT skills ranked the most difficult aspect of online learning in Egypt while recorded lectures ranked the most commendable way of online education delivery. Further findings revealed that the majority of education leaders recommended online distance education; and this led the Egyptian government to decide on incorporating both face-to-face and online learning into all future higher education plans. This, is believed, will make the country better positioned to deal with emergency situations like Covid-19. This will most importantly achieve crucial education goals such as reducing student density on campus, making the best use of professors’ expertise and IT infrastructure while gradually transforming students to lifelong learners. It was also reported that the move from contact sessions to online platforms did not lead to significant devastating learning experiences for students in Egypt. For example, an investigation carried out by El Said (2021) in one university in Egypt compared the academic grades of 376 business students who completed a face-to-face course in the spring of 2019 and the grades of 372 who completed the same course in the spring of 2020, but via online distance learning and under lockdown. The findings showed that there was no significant difference in the grades of students in the two groups and that the sudden move to online learning did not result in poor learning experience outcomes.

South Africa

On the March 5, 2020 South Africa recorded its first COVID-19 case. Within three weeks, the country was in total shut-down level five that brought everything to a standstill, not only in South Africa but also globally. South Africa was one of the countries that introduced the strictest country-wide lockdown actions beginning from March 26, 2020. The country also turned to online lessons to save the academic year. In the context of South Africa, online teaching and learning was not a novel idea. Before Covid-19, many universities had engaged in some form of hybrid or blended learning that combined face-to-face models with online models (Le Grange, 2020). Students and lecturers were familiar with the use of Learning Management Systems (LMS) and possessed the basic skills to at least upload and download course materials (Le Grange, 2020; Du Preez and Le Grange, 2020), access module information, continuous assessment, and exams marks, etc. For example, the University of Pretoria adopted the use of the online system known as Blackboard and branded as ClickUp while the University of Johannesburg makes use of Blackboard module. These functions of the LMSs were expanded to include live online lectures delivery (which could also be watched or downloaded at a later time), pre-loaded recorded lectures and online assessments, in order to aid the transition from face-to-face to virtual sessions. The new context of the pandemic required of both students and academics to have advanced technological skills and digital literacy levels for a full migration to virtual sessions during the pandemic. As Le Grange (2020) notes, some South African universities exhibited zeal, commitment, and passion to save the academic year by embracing the slogan “no student left behind” as their organizing and rallying theme. Innovative strategies to support students in ensuring that none of them is left behind include the following:

Universities purchased and loaned laptops to indigent students; made available data vouchers so that students can be able to connect to online services, those that did not have access to or reliable electricity supply were allowed to return to campus and residences so that they could continue with their online academic activities. The Department of Higher Education training (DHET) also came on board to support universities by negotiating with telecommunication companies to provide affordable pre-paid data packages and zero-rated data to students and staff. The zero-rated data enabled students and staff to access universities’ major websites, libraries websites and Learning Management Systems. However, Du Preez and Le Grange (2020) raised two concerns about online teaching and learning. The first was the promotion and support of unequal access to data, connectivity and technology in an already unequal society as South Africa, thereby raising the issue of distributive justice. Secondly, they raised concerns about epistemological access, as access to technology does not guarantee that all students have access to the knowledge that the university distributes. Students and student leaders also raised concerns about marginalizing students who lived in areas with poor internet connectivity and lack of electricity that would hinder them from effectively participating in online lessons. In response, to the concerns of students (and some staff members) and coupled with the commitment universities made to ensure that no students would be left behind, various universities utilized various means to address this problem. For example, the University of Cape Town, disbursed printed learning materials and USB drives to students who had no internet access at all (Petersen, 2020). The University of Pretoria couriered paper based learning materials, at huge cost, to students who were based in areas without internet services and electricity; and appointed tele-tutors to support those students. Tele-tutors made weekly telephone calls to students to support check on the progress of their studies.

Furthermore, Mphahlele et al. (2021) found out that some of the students in South Africa higher education had limited digital knowledge in Learning Management System. This impacted on the ability to meaningfully participate in the teaching and learning activities.

Nigeria

Nigeria operates a federal system of government with 36 states and the Federal Capital Territory of Abuja. The 36 states are made up of 744 local governments and education is managed by the federal, state and local governments. However, the Federal Ministry of Education is responsible for overall policy formation and ensuring quality control, but primarily involved with higher education. The higher education system consists of the university, polytechnics, monotechnics, and colleges of education (Jacob et al., 2020).

Although the first case of COVID -19 case was confirmed in Lagos, Nigeria, on 27 February 2020, it was only in March 2020 that Nigeria followed the global trend of shutdown of schools and universities in order to curb the spread of COVID -19 pandemic (Jegede, 2020).

Several studies that explored the impact of COVID-19 include positive responses from private university lecturers in navigating the use of technology in online learning (Ojo Joseph et al., 2021). According to Jacob et al. (2020), COVID-19 pandemic caused reduction of international education, disruption of academic calendar, cancellation of local and international conferences, teaching and learning gap, loss of workforce, and cut in budget of higher education in Nigeria.

The COVID-19 situation in Nigeria was worsened by the strike action of lecturers at public universities that was led by the Academic Staff Union of Universities (ASUU) which began on March 23, 2020, a few days before the closure of schools and universities nationwide. Unfortunately, the strike action lasted nine months, which led to the loss of the 2020 academic year (Uchendu et al., 2021).

Unlike countries such as South Africa and Egypt, many higher education institutions in Nigeria, especially public or government-owned universities, could not migrate to online teaching and learning during shutdown in March 2020. This is because hybrid learning and the incorporation of Information and Communication Technology into teaching and learning in public universities

had neither been popular nor successful. In addition, Egielewa et al. (2022) reported that due to poor electricity connectivity and internet accessibility in Nigeria, online learning during the COVID-19 pandemic was ineffective. This showed that Nigerian higher education students preferred the traditional classroom to online learning.

In another study conducted by Jegede (2020) the findings suggest that online learning can be an alternative measure to face to face learning in future pandemic situations.

However, Yunusa et al. (2021) reported challenges in using technology during online learning. These include lack of skills among personnel and students and poor or lack of digital technology infrastructure.

Yet in another study, Abosede et al. (2021) recommend that government should provide more technological infrastructural development in higher institutions while existing ones should be upgraded to meet the global standards.

Kenya

In Kenya the government ordered the closure of all schools and universities as a measure to mitigate the spread of the virus, just like other countries had done. Between March 15 and July 17, 2020, learning continued remotely and through home schooling. Most institutions leveraged television, radio broadcast, distance learning, online learning and gamification, to continue with the academic year with view to save the academic year (Kathula, 2020). Other commendable initiatives, applauded by university stakeholders were also taken by some universities to ensure the academic year was not lost and that teaching and learning reached a wider range of students. For example, the University of Nairobi made thousands of learning resources available remotely through electronic sources (Kathula, 2020). The Ministry of education also launched few strategies to ensure learning continuity, which include the broadcast of educational programmes via television, radio and YouTube (Ngwacho, 2020). The Kenyan government also partnered with Kenya Publishers Association to make free textbooks available to all students on the Kenya Education Cloud. In addition, the Kenya Civil Aviation Authority, on behalf of the Kenya government, partnered with Telkom Kenya to deploy Google's loon balloons of 4G base stations over Kenya's airspace. In spite of these laudable efforts to ensure no student was left behind during the pandemic, access of all students to these services remained a problem. As in many of African and developing countries, the deep-rooted issues of inequality and access in the society were brought to bare (Ngwacho, 2020). As a result, and coupled with the rising number of infections in the country, the Kenyan ministry of education announced the forfeiture of the 2020 academic year as a way of containing the virus. This had an adverse effect on the education of over 17 million students in Kenya.

Although the higher education in Kenya adapted to e-learning during COVID -19 pandemic, navigating through the pandemic was met with several challenges. Some of the challenge include: inadequate Information and Communication Technology (ICT) infrastructure, lack of technical and pedagogical competencies and training for e-tutors and e-learners, negative perceptions toward e-Learning, and domination of e-Learning aims by technology (Kibuku et al., 2020). Kathula et al. (2021), point out how students in remote and rural areas had challenges participating in online learning due to poor internet connection. Their challenges and grievances include excluding their marginalized peers with little or no access to internet services and those with no money to buy laptops (Wekullo et al., 2022).

Vegas and Winthrop notes that less than 25% of low-income countries in Africa had the capacity for some form of remote pedagogy, the majority of which were television and radio; compared to about 90% of high-income countries that had the capacity for remote pedagogy (Vegas, 2020). Many countries in Africa, even those who had no capacity for any form of internet-based teaching learning were also innovative in their approaches. They engaged some offline technology such as text messages and basic phone calls to ensure that learners in rural areas were not excluded. For instance, a national survey conducted about three weeks after leaning institutions were closed down in Senegal showed that school closure reduced learning and increased inequalities. Most learners could not continue their education via any technological platform, mainly TV and radio, but relied on parental support to continue learning (Le Nestour and Moscoviz, 2020).

Cases of selected African countries

The Democratic Republic of Congo (DRC) is one of the countries in central Africa that felt the devastating impact of COVID-19 pandemic in higher education (Sasidharan and Dhillon, 2020; Jacobs et al., 2021). It is on record that DRC experienced Ebola outbreak in 2014 and 2019–2020 (Lee et al., 2020). The outbreak of COVID-19 in 2020 was yet another blow on the country's higher education especially in their medical institutions (Échochard et al., 2021).

Sasidharan and Dhillon (2020) noted that as higher institution switched to online classrooms and blended learning approach globally, the medical institutions in DRC changed to the "Webside of Telemedicine", and Competency Based Medical Education (CBME). Although Karemere and Makali (2022) argue that distance learning determine pedagogical continuity during pandemic but cannot be a sustainable and generalized form of teaching. Sasidharan and Dhillon (2020) also reiterate that adapting to this "new—normal", of integration of technology in the medical institution negatively impacted the use of human skills like compassion and empathy which form the core cultural values of DRC and are critical in patient care.

In Ethiopia, Tamrat (2021) noted that navigating through the pandemic with the use of technology was very difficult especially where there is limited or no internet access. "Poor internet access, cost, availability of computers and related technology, little preparation, and the use of information and communication technology stood out as the most prevalent problems" (Tamrat, 2021, p.

66). Meanwhile in Sub-Saharan Africa [Aborode et al. \(2020\)](#) reported the impact of the pandemic in higher education as most of the students do not have access to home computers for online learning.

Meanwhile in Ghana, [Owusu-Fordjour et al. \(2020\)](#), reiterate the lack of the technical knowhow in the use of these technological devices by most Ghanaian students and the inability of most students to study independently as their parents could not assist them in their studies as the challenges experienced during the pandemic.

It is evident from the above analysis that while some African countries and learning institutions successfully transitioned to online mode of education delivery, others struggled, given the digital divide and underdeveloped technological infrastructure in Africa. The next section discusses some the implications brought about by the pandemic which which can be harnessed to build a stronger education system post Covid-19.

Implications the pandemic for the future planning

The innovative ways with which countries around the world, especially under-resourced African countries engaged their educational systems during the pandemic strongly suggest has implications for how to better plan for future pandemics. It is true that the pandemic has been tough, having adverse effects on individuals, families, societies and almost all sectors, including education. Nevertheless, we must brace up for life post-Covid 19, look beyond the difficulties and embrace the opportunities therein. The [United Nations \(2020, p. 4\)](#) rightly advises that, “the massive efforts made in a short time to respond to the shocks to education systems remind us that change is possible. We should seize the opportunity to find new ways to address the learning crisis and bring about a set of solutions previously considered difficult or impossible to implement.” In the sections that follow, we discuss the implications the pandemic has which could be harnessed to accelerate sustainable educational systems in Africa and globally.

Advancing meaningful partnerships

There have been calls for stronger and more meaningful partnerships amongst educational institutions, governments and private organizations ([Le Grange, 2020](#); [Ngwacho, 2020](#); [Vegas and Winthrop, 2020](#)). These partnerships offer some unique opportunities for all stakeholders to provide continuous and sustainable support to learners to access quality education, and not only at a time of crisis. These could include the provision of free devices, internet connectivity, textbooks and learning resources to students. This would make universities to be better equipped to cater for the educational needs of various students from different contexts. The move toward partnership is exemplified by the [UNESCO's \(2020\)](#), “Save Our Future” campaign, a global education coalition, that advocates for sustained education funding by international donors, for low and middle income countries. Multilateral partners such as the World Bank and the International Labor Organization, private companies such as Microsoft and Google, non-profit organizations such as Dubai Cares and Sesame Street, and media outlets such as the British Broadcasting Cooperation (BBC) world service have all joined the coalition to alleviate the adverse effects of school closure, especially on the most disadvantaged. Similarly, [Vegas and Winthrop \(2020\)](#), note that the closure of learning institutions witnessed partnerships between teachers and parents (the pandemic has proven that parents are strong allies in their children's education), community health workers and social welfare organizations, media companies and education leaders, technology companies and governments, non-profit organizations and businesses, all worked together to assist students like never before.

Advancing technological infrastructure

A study conducted by [Magesa and Josua \(2022\)](#) recommend more investments to widen access to information communication technology (ICT), and to promote inclusivity and massification in higher education despite internet challenges in Africa.

Covid-19 brought about the largest online teaching and learning movement in the history of mankind. There are strong indications that online teaching and learning would outlive this pandemic and constitute a significant part of educational programmes at universities post Covid-19. As discussed earlier, the responses of institutions around the world, and in some African countries, to ensure that the 2020 academic year was not thwarted were laudable. The pandemic has proven that Africa needs to develop its own technological infrastructure to be better positioned for not just a time of crisis, but also as a normal practice in teaching and learning ([Ngwacho, 2020](#)). [Vegas and Winthrop \(2020\)](#) argue for the smart use of technology and data, without replacing analog approaches. They further argue that the innovative use of technology, especially mobile phones—as an example of strategies that have emerged during the pandemic, could complement teaching and learning if sustained.

[Le Grange \(2020\)](#) notes that the Covid-19 pandemic could herald a new ranking game that would assess universities based on how well they are positioned for online teaching and learning. He further sees the pandemic as an opportunity for universities to increase investments in online education delivery, and that he foresees historically advantaged institutions leading the race while others play a catch-up game. Meanwhile, [Hodges et al. \(2020\)](#) warn against a low quality of courses offered because of swift adoption of online mode of education. Rather, online teaching and learning should be well-planned and meaningful to harness its full benefits. That said, technological efforts might not be sustainable if educators and learners are not supported to embrace the benefits of technology.

Innovative modes of education delivery

Du Preez and Le Grange (2020) and Vegas and Winthrop (2020) have called for an emphasis on the heart of the teaching and learning process, which Vegas and Winthrop (2020, para. 25) refer to as the “instructional or pedagogical core”. This implies that the way educators engage with students, educational technology and educational materials is crucial for learning, considering that educators are the most important role players in determining student learning. Simply put, instructional core is the interaction between educator, learners and educational materials. For example, high quality learning materials will not on their own elicit quality learning experience, until educators effectively engage them for teaching. According to Vegas and Winthrop (2020), one of the reasons many education innovations failed, despite painstaking effort, is because inadequate attention is not given to instructional core.

Addressing issues inequality, equity, and access in educational systems

The pandemic accentuated the already existing issues of equality, distributive justice and epistemic access in African societies. In relation to epistemic access, Du Preez and Le Grange (2020) argue that ensuring epistemic access in the time of emergency remote teaching (ERT) demand a great deal of work from academics. Lecturers need to bear in mind the various contexts in which students are learning. To therefore ensure epistemic access during and after Covid-19, “an expended notion of emergency remote teaching and learning” (Du Preez and Le Grange, 2020, p. 12) must be considered. This will involve employing other forms of learning to complement online teaching and learning such as interactive print materials and repository texts.

Du Preez and Le Grange (2020), clarify that face-to face teaching and learning does not guarantee epistemic access, neither does it remove historical disadvantages; nevertheless, it at least provides a levelling ground for all students to have the same access to the resources provided by a university, which might be harder to achieve through online teaching and learning. Universities should therefore devise strategies to ensure that students’ epistemic access during online teaching and learning match up with what is obtained during face-to-face sessions, if it cannot surpass it. Vegas and Winthrop (2020) do expect that education systems would be transformed in a way that they address inequality and enable all young people to acquire the skills needed to build a better future for themselves and their communities. Many proponents of education also have high hopes that a more equal education would emerge out of the pandemic.

Conclusion

This chapter has analyzed how African countries have navigated the pandemic and the implications for how the countries around the world can better plan for possible future pandemics. The shift from face-to-face contact to online learning allowed higher institutions to pursue the aspects of technology-based learning they have found most useful (Ali, 2020; Daniel, 2020). Covid-19 did not only show how higher education navigated the pandemic with the use of technology, but it also demonstrated the inadequacies and unpreparedness of the higher education systems in Africa to deal with the pandemic (Mutinda & Liu, 2021; Bolumole, 2020; Demuyakor, 2020). However, Kopp et al. (2019) believe the environment is optimal for digital transformation of higher education.

Muftahu (2020) also noted that the challenges caused by the Covid-19 pandemic have influenced opportunities to practice online and distance learning, with immediate and long-term changes that can transform the overall education system beyond the Covid-19 pandemic for the better. Although this chapter noted some challenges in access to technology and usage in higher education in Africa, it appears that the social, and mental health issues of students associated with the pandemic were some of the contributing factors to their inability to use the available technology (Owusu-Fordjour et al., 2020; Zhai and Du, 2020).

African higher education systems have come through a complex historical path of challenges and transformations and these dynamics seems to have created an imperfect Africa (Woldegiorgis, 2021). Covid-19 has forced innovations into the core functions of almost all education systems (Vegas and Winthrop, 2020). Reimers and Schleicher (2020), based on their survey of educators and education administrators in 59 countries, equally submit that the pandemic has revealed the massive possibilities for innovation which were previously dormant in the education systems. However, we wonder how technological innovation will be possible in Africa with so much diversity and inequalities. In this regard, Toure (2021) suggests that applying a diversity, equity, and inclusion lens to all policies and programs at national and regional levels will assist in the embracing of technological innovation and making it a reality. In addition, with the advancing of the Fourth Industrial Revolution (4IR) and developing environment in which technologies are changing how we live and work (Kayembe and Nel, 2019), Mahlaba (2020) advocates the need for self-directed learning during pandemics.

Similarly, Tamrat (2021) added that although there are evidently long-term effects of COVID-19 on higher education, there are some challenges in access to technology and usage in higher education in Africa. These developments have implications for and provide lessons for how governments should think about future plans for the development of their societies in general, and education in particular, in order to be better prepared for deal with future pandemics. In a world that is characterized by inequalities, in inequities and injustices; and is vulnerable to global hazards such climate change and regional wars, there is a need for more commitment to United Nation’s sustainable development goals (SDGs) in order to bring about a better world that is more equal and just. In this was, we will be better able to deal with future pandemics and associated world disasters.

Introduction

Pandemics—defined as large-scale outbreaks of infectious diseases that can greatly increase morbidity and mortality over a wide geographic area and cause significant economic, social, and political disruption—have increased in number over the past century because of increased global travel and integration, urbanization, changes in land use, and greater exploitation of the natural environment (Madhav et al., 2017). Since December 2019, COVID-19, a highly infectious disease caused by a new virus, has had an increasing impact on countries and regions around the world. Starting initially as a health crisis, the COVID-19 pandemic has quickly shown a socio-economic dimension (PWC, 2020). Consequently, schools, universities and other higher education institutions have been forced to suspend campus-based operations, such as teaching and research, with significant impact on countries' competitiveness and their ability to foster advanced skills and regional development (Arnhold et al., 2020).

Among the measures targeted at limiting the spread of the virus have been: bans on large gatherings, remote working and schooling, prescribing hygiene protocols at home, in hospitals and public places, through the use of masks and protection equipment, and cleaning of public spaces (PWC, 2020). A large number of schools and educational systems have had to adopt internet-based methodologies to support their students via distance education solutions during the period of school closures (WHO, 2020a), making disparities in distance education more evident in its wake. The risk of growing inequality is emerging also from the results of regional analyses, with higher education institutions in Africa reporting more difficulties and negative effects than higher education institutions in other regions. These divides, laid bare by COVID-19, are a major obstacle in the drive for inclusive and equitable access to higher education by 2030, which is a target of Sustainable Development Goal 4 (ACU, 2020).

In this article, we take a look at the higher education landscape in Africa, examining disruptions to education caused by the COVID-19 pandemic outbreak, and the key educational processes affected, including higher education business. We do this through a desktop analysis of secondary data wherein systematic literature, policy documents, as well as related models between COVID-19 and higher education are reviewed. With this review, we aim to contribute to the discussion, by recording how the various stakeholders within higher education responded to the pandemic and highlighting the real and estimated effects of the pandemic on higher education institutions, consequences and lessons of the responses to the pandemic.

Higher education in Africa

Higher education serves as the principal venue for knowledge creation and economic and social development (Aina, 2010) and occupies a very special place in any society's development due to its function of fostering the capacity of individuals and communities to promote sustainable development. As aptly described by Teffera and Altbach (2004, p. 3), higher education in Africa is "as old as the pyramids of Egypt, the obelisks of Ethiopia, and the Kingdom of Timbuktu." Higher education in Africa plays a critical capacity building and professional training role not only in national development but also in support of all the Millennium

Development Goals (MDGs) (Materu, 2007) and subsequently, Sustainable Development Goals (SDGs). Its central role in the economic and political development of the continent in an increasingly globalizing knowledge society is widely acknowledged (Cloete et al., 2011).

Globally, the pressure on higher education systems to provide access will continue unabated in the years to come due to the rapid growth of the sector, particularly in Asia and Africa (Bloom et al., 2005). Major transitions and reforms in African education systems have taken place focusing on access, equity, quality, affordability and relevance to the national philosophy and needs. Various policies and legislations have been put in place to enhance the expansion of higher education institutions, through both public and private means, to meet the aspirations of rapidly growing national populations and economies.

Pandemics

The late 20th and early 21st centuries have seen the rapid transmission and difficulty of containing various diseases. There have been five global health emergencies since 2005 when the declaration was formalized: swine flu in 2009, polio in 2014, Ebola in 2014, Zika in 2016 and Ebola again in 2019 (Mhlanga and Moloi, 2020). According to Bloom et al. (2020), many epidemics and pandemics are ongoing, claiming millions of lives per year (such as HIV/AIDS, malaria, and tuberculosis); some are on the rise in terms of infections and deaths (such as dengue fever and various forms of hepatitis); some have nearly been eradicated but with a dangerous prospect of re-emerging should containment efforts be relaxed (such as measles and poliomyelitis); some have abated or were successfully contained (such as SARS, Ebola, H1N1 influenza, and Zika); and some have frequent outbreaks (such as cholera).

But what exactly is a pandemic, and how does it differ from other terms usually used in health cycles—epidemic, endemic, and outbreak? According to the World Health Organization (WHO, 2020a), an epidemic is a disease that affects a large number of people within a community, population, or region. A pandemic, on the other hand, is an epidemic that has spread over multiple countries or continents, defined by the Merriam-Webster dictionary as a global outbreak of a disease from a new virus. An outbreak is defined by WHO (2020a) as a greater-than-anticipated increase in the number of endemic cases, an endemic being something that belongs to a particular people or country (WHO, 2020a). A pandemic, therefore, is an epidemic occurring over a very wide area, crossing international boundaries, and usually affecting a large number of people. Accordingly, pandemics are identified by their geographic scale rather than the severity of illness, and the term is used to describe a disease that affects a whole country or the entire world (Centers for Disease Control and Prevention, 2020; Madhav et al., 2017; WHO, 2020a). For example, in contrast to annual seasonal influenza epidemics, pandemic influenza is when a new influenza virus emerges and spreads around the world, and most people do not have immunity (WHO, 2010). Pandemics, therefore, are large-scale outbreaks of infectious disease that can greatly increase morbidity and mortality over a wide geographic area and cause significant economic, social, and political disruption.

Multiple outbreaks have exposed gaps related to the timely detection of disease, availability of basic care, tracing of contacts, quarantine and isolation procedures, and preparedness outside the health sector, including global coordination and response mobilization (Moon et al., 2015; Pathmanathan et al., 2014). These gaps are especially evident in resource-limited settings and have posed challenges during relatively localized epidemics, with dire implications for what may happen during a full-fledged global pandemic (Madhav et al., 2017). Evidence suggests that the likelihood of pandemics has increased over the past century because of increased global travel and integration, urbanization, changes in land use, and greater exploitation of the natural environment (Jones et al., 2008; Morse, 1995). These trends are likely to continue and will intensify (Madhav et al., 2017). Significant policy attention has focused on the need to identify and limit emerging outbreaks that might lead to pandemics and to expand and sustain investment to build preparedness and health capacity (Smolinsky et al., 2003).

The emergence and rapid transmission in the late 2019 and early 2020 of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and the steep increase in the prevalence of the disease it causes (coronavirus disease 2019 or COVID-19) forcefully reminded scientists, policymakers, and the wider public of the world's vulnerability to infectious disease pandemics (Bloom et al., 2020). Within a few weeks, we moved from a few reported cases of a new pulmonary disease in the city of Wuhan in China to a state in which almost all countries reported infections and deaths, billions of people could only leave their homes for essential purposes, economic activity nosedived, and unemployment figures skyrocketed.

However, the international community has made significant progress toward preparing for, and mitigating, the impacts of pandemics. Crawford (2020) characterized four phases of pandemic response: rapid adaptation, improvement, consolidation, and restoration. The goal of the first phase is "to rapidly adapt core business for the new context"; the second phase is "to optimize the adapted core business to improve quality and begin to consider non-core activities"; the third phase is "to evaluate pre-pandemic measures of social, economic, and environmental success"; and, the fourth phase is "to determine what a return to business-as-usual looks like, and how it can occur" (Crawford, 2020, n.p.). It is recognized that institutions will likely go through these stages at different speeds, and some institutions may move fluidly between phases. Likewise, it is possible for an institution to exist inside of two phases, depending on their method of engagement and organizational strategy (Butler-Henderson et al., 2020).

Impact of COVID-19 pandemic

Since COVID-19 is not just a medical pandemic, but a social event that is disrupting our social order, tackling it has presented a humanitarian and development crisis that is threatening to leave deep social, economic and political scars for years to come (Teti et al., 2020). The education sector has not been immune from the impact of COVID-19, as it has affected all levels of global education systems from the pre-school to the university and has caused cancellation or postponement of academic conferences (Oyedotun, 2020). Several individuals, organizations and national entities have conducted surveys on the impact of COVID-19 on higher education at the institutional, national, regional and global levels. Other studies have been undertaken by academic researchers to understand the economic impact of this pandemic. Bloom et al. (2020) discuss and review literature on the macro-economic effects of epidemics and pandemics since the late 20th century. Philipson (2000), Malani and Laxminarayan (2011), Klein et al. (2007), Gersovitz (2011) and Rasul (2020) have all conducted surveys on the economics of infectious diseases with more focused treatments of the earlier literature. Brodeur et al. (2020) provide a survey of the emerging economic literature on COVID-19, and a wealth of research has been published as part of the Center for Economic Policy Research's "COVID Economics" series of vetted and real-time papers (Wyplosz, 2020). From all these studies, key issues have emerged that may be used to evaluate the exact impact of the COVID-19 pandemic on the various aspects of higher education.

Responses to the COVID-19 pandemic

The COVID-19 pandemic has highlighted the importance of rapid and well-coordinated responses to a global situation that has put pressure on every aspect of the health system, education, research, and practice (Lackie et al., 2020). Poor emergency responses were seen in the beginning of the outbreak (Muftahu, 2020), with some national governments underplaying the severity of the pandemic. In terms of policy responses, countries tended to limit themselves to three areas: (a) administrative measures to safeguard the operation of the system; (b) financial resources; and (c) the provision of resources to continue education activities (UNESCO-IESALC, 2020). Immediate economic responses implemented by countries can be highlighted in four categories, namely, restriction of movement, health measures, social measures and economic measures taken to reduce the socioeconomic burden on citizens while paving the way for economic recovery (AUC, 2020). From the beginning, institutional responses have covered different areas: the strictly health front, the adjustment of calendars, research and development contribution to mitigate the pandemic, the guarantee of continuity of teaching activities through distance education, bibliographic and technological resources, as well as socio-emotional support to the university community (UNESCO-IESALC, 2020).

Immediate responses to the COVID-19 outbreak within most countries have been developed primarily to control and curb the spread of the infection, and have led to the closure of entire countries (Nkhoma, 2020), as well as measures of social distancing, widespread lockdowns, and restrictions on traveling, movements, and gatherings (WHO, 2020a). From the responses, it is clear that the strategy for dealing with COVID-19 is context-specific as every country and institution is different (Nkhoma, 2020). In their report, the African Union Commission (AUC, 2020) found some striking differences on how COVID-19 is behaving in different countries. For instance, in Italy, there had been strong curtailing of social interactions yet COVID-19 mortality still remained high. In contrast, Japan had some of the earlier cases, but the mortality remained low despite not having adopted some of the more restrictive social isolation measurements. These puzzling differences have been adjudicated to different cultural norms as well as differences in medical care standards. To some extent, therefore, the effectiveness of the governmental responses could explain the difference in the magnitude of the impact of the pandemic between countries. Therefore, individual countries and/or institutions need to develop their own ways to deal with the pandemic (AUC, 2020), including clear social justice principles of accessibility, inclusivity, flexibility, equitability and connectivity (Zezeza, 2020).

Considering the outbreak does not respect borders, the inability of one country to fight and contain the virus will negatively impact its neighbors over time, thus threatening livelihoods and the growth of economies (AUC, 2020). Hence, it was necessary that Africa quickly and effectively develops a coordinated response to collectively fight the impact of the pandemic on the continent. Consequently, in addition to the policy actions at the national level to contain the spread of COVID-19 and mitigate its socioeconomic impact, the African Union has been at the forefront of the fight against the pandemic by coordinating the activities and raising resources to strengthen the continental response to COVID-19, maintain economic activities and revive African economies.

There have also been significant contribution of sub-regional, continental and international bodies in supporting HEIs and governments to respond to the impact of the pandemic through training, collecting data and monitoring the impacts of COVID-19 on higher education, hosting resource pages, recommending policies, and providing support materials for governments and other higher education stakeholders (Agyapong et al., 2020, p. 16). These include the Councils of Tertiary Education, the Inter-University Council for East Africa (IUCEA), the Association of African Universities, Association for the Development of Education in Africa (ADEA), the Regional Universities' Forum for Capacity Building in Agriculture (RUFORUM), the Southern African Regional Universities Association (SARUA), UNESCO, the International Association of Universities (IAU), the World Bank, among others. Furthermore, private companies, particularly telecom companies, are increasingly partnering with TELs and government to overcome the critical challenges by negotiating zero-rated access to specific educational and information websites. For example, in Senegal, dominant ICT player Sonatel has moved to address this issue, giving students the chance to activate a free 1-GB education pass (Agyapong et al., 2020, p. 17). Similar partnership agreements have been made between telecom companies and universities in countries such as Ghana, South Africa and Kenya.

Effect of responses on higher education institutions

In Africa, the policy measures taken by African Union member states have resulted in the disruptions of economic and social activities and the educational system was severely affected due to the total closure of learning institutions, schools, colleges and universities by governments across the continent. By end of March 2020, all African countries but one had countrywide closures of education institutions (AUC, 2020), forcing students out of their physical learning spaces, and confining lecturers and professors to their homes (Lues et al., 2020). The first immediate response to the lockdowns by HEIs has logically been to try to substitute all mobility with virtual activities. Site and exposure visits, training and education, workshops and consultancies have been replaced overnight by Zoom meetings, webinars, distance education and endless Skype calls (Aarts, 2020). Still, the general experience is that virtual cooperation also has many limitations. Moreover, precisely those groups that are often targeted in capacity building efforts, such as socio-economically vulnerable groups, women, girls, youth from poorer backgrounds, etc, tend to be less virtually connected. Now, therefore, is the time for Africa to build internationalization-at-home, by crafting relevant policies and programs, since the COVID-19 crisis calls for enhancing of intra-African mobility as well as internationalizing higher education curricula to attract international students globally (Waruru, 2020a).

While remote work was a feature of multinational firms and open source communities among others, the pandemic effectively forced “all remote all the time”, resulting in a scramble to adapt to remote collaboration and its technological infrastructure (George et al., 2020). The conditions under which higher education all-of-a-sudden had to perform research and what is now often referred to as “emergency online education,” demanded the reskilling of lecturers and instructors in modes of online teaching, assessment and mentorship (Marinoni et al., 2020). Perhaps on a positive note, though, the pandemic has forced universities to devise strategies and solutions to ensure quality provision, and students and higher education institutions have learned to adjust and ensure continued teaching and learning (Makoni, 2020).

Impact on core missions of universities

The traditional mandates of universities revolve around teaching/learning, research and community engagement or outreach. The important question, therefore, is how the COVID-19 pandemic has altered the main processes in education, including academic recruitment, academic management, teaching and learning, study and advancement, student life and welfare; and on the other hand, how COVID-19 has compelled the institutions of higher education to implement new approaches, and to let go of their current teaching practices (Abdullah et al., 2020). With the pandemic pushing education entirely online, universities must acknowledge that the game has changed and try new ways to progress with virtual learning.

Teaching and learning

Teaching and learning have been impacted by the COVID-19 crisis in the most direct way, especially due to the absence of options for face-to-face interactions for an extended period (Arnhold et al., 2020). Before the outbreak, there were only a few fully online universities in Sub Saharan Africa, including the African Virtual University (AVU), the Kenyatta Digital School of Virtual Learning, Laweh Open University, the Open University of Tanzania, and the University of Rwanda's e-learning platform (Agyapong et al., 2020, p. 15). According to the World Bank, these institutions have the existing capacity and experience to offer online programs, but they are mostly targeted toward students who want to upgrade their skills while they are already employed, though their mandates continue to expand (World Bank, 2020).

Whereas some universities that had adequate digital infrastructure have been swift in transitioning to online teaching and learning (Agyapong et al., 2020, p. 14), switching to the online mode of teaching and learning has revealed several global and local challenges that universities are facing right now. Among global challenges, the following are related to the online infrastructure: weakness of internet connection and internet speed in many countries; high prices for a good internet connection; absence of computers and other gadgets that support online teaching and learning; and many online instruments, platforms, and websites crashed when an unexpectedly high number of clients connected to them. With governments and HEIs adopting remote teaching to support distance learning and online education delivered through ICT, learners from poor, vulnerable and marginalized households have no access to these mediums of learning, further worsening inequality in access and quality of education (Areba, 2020). In order to mitigate this, most faculty had to do significantly more work to move courses online, rethink curriculums and assessment, learn to use software and technology for teaching and learning, and make sure that all their students were included and were coping.

On the other hand, the COVID-19 outbreak accelerated and forced the adoption of digital solutions at an unprecedented pace, creating unforeseen opportunities for scaling up alternative approaches to social and economic life (Hantrais et al., 2020), despite the digital risks and threats (Giordani and Rullani, 2020). The intense exploration of digital tools and their applications caused by COVID-19 represented a leap that would have taken years to be realized in normal times (George et al., 2020), due to experimenting without any safety net. Schwab and Malleret (2020) acknowledge that the world was facing a “defining moment” as the pandemic precipitated the fusion of technologies, enabling digital technologies to extend their reach, almost uncontrolled, into every aspect of life.

The transition to online learning has laid bare the digital divide within the African continent—between those countries that have better ICT infrastructure than others; between higher education institutions within the same country, with some being far better equipped and experienced than others; and between students within the same institution; the rich who live in urban areas; and the poor in rural areas who can barely afford to access the internet, when and if it is available (Mohamedbhai, 2020). To mitigate

the challenges that come with the digital divide, some African HEIs in countries such as Ghana, South Africa, and Rwanda among others, partnered with Telco's to zero-rate these platforms in some instances facilitating universities to make data packages and laptops available to some students to improve access (Agyapong et al., 2020, pp. 14–15).

Research

The most common impact of COVID-19 has been the stoppage of many scientific research projects, canceling of international travel and postponement of scientific conferences (Marinoni and de Wit, 2020). The pandemic has particularly affected early career researchers (ECRs) for whom precarity has manifested in many ways (Hooper and Djerassimovic, 2020)—from uncertainty regarding how they will support themselves when they do not complete their doctorate within prescribed timeframes, to the insecurity of undertaking multiple fixed-term contracts as postdocs (McKie, 2020). A recent survey (Vitae, 2020) highlighted that around two-thirds of ECRs are very worried about their future and finances, with only 10% of those whose contracts would end in 2020 having been granted extensions in the context of the pandemic, and only 12% of final-year doctoral students reporting that their institution had provided an option to extend their studies.

One of the few positives, however, has been the speed at which many global partners joined to battle the disease (Ferdig et al., 2020), with academic researchers, and even academic journals, joining in the fight. For instance, in addition to giving open access to articles, many medical journals switched to a speedier review to be able to quickly publish promising results. Therefore as researchers were making early discoveries, they had a way to bypass a traditionally longer review and publication process to give hope, share building blocks, and encourage collaboration.

Outreach

For the large majority of HEIs, COVID-19 has impacted their community engagement initiatives, but largely in positive ways—the crisis has increased HEIs' community engagement (Wachira and Ombati, 2020). African universities have responded to the pandemic with many innovations to solve local problems, with many public universities directly helping to fight the pandemic in different innovative ways—producing much-needed hand sanitizers and face masks, developing a prototype ventilator that could be affordably mass produced, undertaking joint vaccine research with other partners, developing a variety of COVID-19 fighting tools including a portable solar-powered ventilator, a contact tracing mobile application and an automatic solar-powered hand-washing machine. These universities are being true to their visions and missions and doing exactly what society expects them to do. On the e-learning front, some public universities have been doing fairly well (Wachira and Ombati, 2020), with a number of them already having active online and distance learning departments and were not necessarily starting from scratch during the pandemic. Many had already invested in e-library resources where they subscribed to various e-books and e-journals that are especially useful to their postgraduate students.

Regarding partnerships, many universities around the world have traditionally supported, in one way or another, partner institutions in poorer countries and regions, often in the Global South. Usually the aim is to strengthen the capacity of these partners to offer higher education of good quality, to underscore local development agendas and, along the way, contribute to the global sustainable development agenda. However, the COVID-19 crisis has forced universities everywhere into crisis mode overnight and meant that they have had to focus on keeping their own education and research running in the first instance, and capacity building efforts supporting far-away partners tended not to be part of the core concern (Aarts, 2020). In addition, funding for such efforts became less reliable as the upcoming economic crisis has affected international cooperation budgets. There is now recognition of the need to strengthen both local and regional collaborations, while leveraging the existing, strong international collaborations that many institutions have (Lues et al., 2020). The multi-, inter- and trans-disciplinary approach should foster closer collaboration between academia and university business entities and support the representation of academia on wider societal platforms. Further, partnership projects between universities and the private sector and civil society organizations are encouraged.

Economic impact

What started as a health crisis has quickly precipitated into a worst economic, social and humanitarian crisis, disrupting millions of people's livelihoods, affecting poor households and damaging formal and informal businesses and government revenues around the world (AUC, 2020). According to SPAU (2020), the socio-economic impact of the COVID-19 pandemic operates through two distinct channels: first are the direct and indirect effects of the sickness, which results from when an income-earner in the household falls ill, and the ratio of active members to dependents falls; second are aversion behavior effects resulting from the fear of catching the virus, which in turn leads to a fear of association with others and reduces labor force participation, closes places of employment, disrupts transportation, motivates some governments to close borders and restrict entry of citizens from afflicted countries, and motivates private decision makers to disrupt trade, travel, and commerce by canceling scheduled commercial flights and reducing shipping and cargo services.

The African Union Commission report (AUC, 2020) projected that the global economic activity would contract by 6% in 2020 (optimistic scenario), and 7.6% (a second wave of infection before the end of that year, according to OECD), while WEO estimated a 4.6% fall, much worse than during the 2008/2009 financial crisis, as per the most recent estimates by the IMF World Economic Outlook for June 2020. For HEIs, the pandemic would have immense financial consequences, as universities are faced with massive losses in revenues after shifting learning online, with queries arising over whether or not all students would return

from their home countries after the pandemic (Halterbeck et al., 2020; Maslen, 2020). For one, it became unclear whether universities could continue charging normal fees for programs that had shifted online, especially for those who had paid for face-to-face learning. At the same time, universities had already suffered very significant revenue losses in respect of accommodation, conferences, and events activity. Furthermore, due to the pandemic, the ability of parents to pay fees as before was likely to be lower, affecting universities' finances.

While public universities might have a strategy for accessing support to deal with reopening, the private institutions are less likely to have access to such funds. However, budget cuts are still to be expected for higher education funding moving forward particularly for public universities mainly because a number of economies are still recovering from the past global financial crisis (Jegede, 2020). Consequently, there is a growing need for universities to reduce their dependence on external funding and international philanthropy and pursue sustainable, locally-focused funding strategies. There is need for universities in the region to closely examine the tenets of "Africapitalism", an economic philosophy developed by Elumelu (Dell, 2020) predicated on the belief that Africa's private sector can and must play a leading role in the continent's development.

For many universities and countries, international student tuition fees are a critical source of revenue (AUC, 2020). However, under the pressure of the pandemic, promoting global mobility has become an emerging issue in higher education settings. Although various methods of enhancing student mobility have been implemented, little research has as yet confirmed the pandemic challenges for students (Wu et al., 2020). Furthermore, the COVID-19 pandemic has come with a lot of uncertainties for the higher education sector and for internationalization and mobility (Waruru, 2020b), including bringing in new conditions such as COVID-19 vaccination compliance certificates targeted at Africa, possibility of racial discrimination (e.g., as seen in the "black lives matter" movement), with learners from poorer parts of the world that mainly act as sources of international students being seen as "unsafe".

The immediate impact of COVID-19 on income and financial circumstances of students shows how many students are living in a fairly precarious financial situations, where it only takes a small change for many of them to suffer extreme financial hardship (O'Malley, 2020). In addition to financial challenges and concerns about degree completion, many students are experiencing stress and anxiety related to the cost of living, loss of income and increasing demands as parents, children and community members (Jaramillo and Stephenson, 2020). For international students, "taking a semester off" has visa implications and may require leaving the country of their studies. Moreover, for students who live in university housing and residences, taking a break would jeopardize their housing situation.

Effect on inequalities within faculty and student demographics

The COVID-19 pandemic is transforming society in profound ways, often exacerbating social and economic disparities and inequalities in its wake (Engzell et al., 2020), and revealing, reinforcing, and catalyzing new social and cultural relations, laying bare inequalities and anxieties, discrimination and division (Leach et al., 2020). The pandemic has exposed "fault lines of inequalities", both in society and in higher education institutions (Waruru, 2020b), revealing the glaring inequalities of access along the differentiations of class, gender, ethnicity, religion, age, location and other social markers (Zezeza, 2020). An equality agenda therefore needs to be supported everywhere in order for the innovation needed to rebuild our society is done by and with all, and not only by those who will be able to afford it (Marinoni et al., 2020).

As HEIs prepare to resume activities fully, they must take into account the fact that increased vulnerability to COVID-19 may pose a challenge for some of their older staff members (Odhiambo, 2020a). According to the United States Centers for Disease Control and Prevention (2020), older adults (60 years and above) are at a higher risk of falling victim to COVID-19 and suffering more serious symptoms. However, throughout the world universities are characterized by significant numbers of older people—senior professors, deans, principals and vice-chancellors—all of whom are recognized as some of the most important people in higher education institutions by virtue of their disciplinary expertise and experience. Strategies must be identified to ensure that the knowledge and experience of the older faculty is not lost, while at the same time ensuring their safety.

On the digital migration front, universities around the world were largely unprepared for a sudden switch to online learning prior to the COVID-19 pandemic—with only a third providing full online courses in some form, according to data collected for the 2020 edition of "U-Multirank." The data showed 60% of higher education institutions reporting online learning provisions in their strategic planning prior to COVID-19, but only one-third appearing to provide full online courses in some form. Some universities, especially those well-endowed financially, were more able to transition to online learning thanks to their superior infrastructure (Mitchell, 2020).

Specifically, Africans are paying some of the highest rates in the world for internet access as a proportion of income, according to an October 2019 "Affordability Report" produced by the Alliance for Affordable Internet. While mobile phone penetration in Africa is very good, including with internet connectivity, there is little accessibility to fixed broadband (MacGregor, 2020), even in Africa's most advanced countries. Many students are still unable to take part in online learning due to a lack of gadgets and electricity, and due to a lack of access to the internet (Waruru, 2020a). These vulnerable students, such as for instance those from less advantaged backgrounds, are especially likely to fall behind during the pandemic period, as they are less likely to have access to relevant learning digital resources (e.g., laptop/computer, broadband internet connection) and less likely to have a suitable home learning environment (Di Pietro et al., 2020). A lot more focus should therefore be given to bridging the digital divide, to ensure that no young African is left behind.

It is projected that the hampering of international student and academic staff mobility by COVID-19 will most likely diminish interest in global rankings. At the same time, national and specialized (by subject) regional ranking are projected to gain importance (Siwinski and Bilanow, 2020). For the very same reason, indicators linked to internationalization of the student body and academic staff may lose some of their weight in the methodology used by rankings, and instead, new indicators related to university presence on the internet will appear. Here, Isidro Aguillo from Spain, who published the first internet-based “Webometrics” ranking as far back as 2004, stands out as a forerunner. According to the “IREG Observatory on Academic Ranking and Excellence,” perception of rankings will likely be shifting in various directions. For instance, prospective students, double hit once by travel restrictions and then by a deteriorating economic situation, will be inclined to pay more attention to national and regional rankings than global.

On the gender front, the UNESCO Global Education Monitoring Report 2020 titled “Inclusion and Education: All means all,” indicates that just 11% of African countries had formulated comprehensive tertiary education equity and inclusion strategies. Noteworthy in the time of COVID-19 is that about 40% of low- and lower middle-income countries had not taken any measures to support learners at risk of exclusion during the crisis (Ligami, 2020). From the experience of the gender impacts of the Ebola virus disease in West Africa 2014–2016, the COVID-19 pandemic would affect women negatively and disproportionately both directly and indirectly due to gender power relations in decision-making (SPAUI, 2020). According to Siwinski and Bilanow (2020), the COVID-19 pandemic has placed young women researchers in a particularly disadvantaged position as female scientists, and especially those with kids, must share time between research and family duties. Furthermore, women often are active in areas of work that are the first to fall away in economic crises (AUC, 2020). As the Ebola outbreak demonstrated, when women have to give up work during times of crises, they will be confronted with more challenges than men when trying to spring back after the crisis. In addition, the COVID-19 pandemic worsened the issue of gender-based violence, which increased by 25% as lockdown measures were implemented (AUC, 2020).

Prolonged school closure and home confinement during a disease outbreak might have negative effects on children’s physical and mental health (Brazendale et al., 2017; Brooks et al., 2020), which might be exacerbated by the lack of peer support and alternatives for mitigation of risks (SPAUI, 2020). Evidence suggests that when children are out of school (e.g., weekends and summer holidays), they are physically less active, have much longer screen time, irregular sleep patterns, and less favorable diets, resulting in weight gain and a loss of cardiorespiratory fitness (Wang et al., 2019). Such negative effects on health are likely to be much worse when children are confined to their homes without outdoor activities and interaction with same aged friends during the outbreak. Furthermore, mental health issues for faculty cannot be ignored as significant numbers of faculty within the region have experienced stress and anxiety brought about by confined lives, increased workload, and job uncertainties (Agyapong et al., 2020, p. 8).

O’Malley (2020) observes that even before the crisis created by the COVID-19 outbreak, data was showing that access and equity remained big challenges in higher education, especially in relation to wealth distribution globally, with Sub-Saharan Africa falling further behind other regions. In 2018, access to higher education in Sub-Saharan Africa averaged about 9% compared to 70% in Europe and Central Asia. The COVID-19 pandemic has increased inequality in African higher education, with digital divide posing even a greater threat to equitable access to education and lifelong learning in Africa (Makoni, 2020). It is generally believed that enrollment, which is already low in African member states, will be further affected with the recognition that the longer children and young people stay away from school, with prolonged school closures, the less likely they are ever to return to school after school reopening (AUC, 2020).

To better understand the effects of epidemics on economic prosperity, knowing the channels by which health affects economic growth in general and the extent to which these channels differ between rich and poor countries is important. A particular challenge for policymakers is therefore to reduce the inequality-increasing tendencies of epidemics when designing policies to cope with epidemic-induced economic downturns (Bloom et al., 2020). In low-income countries, a lack of general access to quality health care, widespread undernourishment, and the prevalence of competing infectious diseases, exacerbate the impact of epidemics. In high-income countries, by contrast, access to effective treatments and a well-functioning health care sector can often mitigate negative health shocks.

Strategies to mitigate COVID-19 effects

As the pandemic continues to ease, it is necessary to assess the magnitude of its socio-economic impact on African countries and identify bold, urgent, medium-term and long-term measures to continue saving human lives and restoring African economies, in order to build a more endogenous and resilient economy to ensure Africa’s self-reliance (AUC, 2020). The educational system has been solid throughout history, continuously functioning in defiance of wars, epidemics, economic hardships and geographical burdens (Al Lily et al., 2020), and this system must now consider roundabout ways to ensure its continuity during, and in the aftermath of, the pandemic. The system does not normally tolerate its discontinuity and abolition, and the tolerance takes place within the sphere of searching for substitutes. Higher education studies (e.g., Butler-Henderson et al., 2020) have emphasized how students and staff are responding to rapid adaptation, how institutions are managing their new commitments and new service landscape, and how institutional responses differ.

Following the move to online or distance learning, availability of resources such as quality IT platforms, fast internet connection, and other computer facilities and equipment are essential (Abdullah et al., 2020). Nevertheless, the forced move to distance teaching and learning offers important opportunities to propose more flexible learning possibilities, explore blended or hybrid

learning and to mix synchronous learning with asynchronous learning (Marinoni et al., 2020). Therefore, universities need to be encouraged and facilitated to offer e-learning pedagogy as an integral part of career-long training for their academics (MacGregor, 2020). Furthermore, COVID-19 has thrown into stark relief the imperatives to bridge the digital divide and to share resources across Africa, and higher education has a key role to play in advancing both of those goals, including by teaching digital skills and collaborating in postgraduate training and research. There is now opportunity to radically revise the curriculum of higher education institutions from every corner to suit remote, distance, online, and digital forms of delivery (Butler-Henderson et al., 2020).

In the outbreak of the pandemic, staff had not been trained to deliver remote learning (O'Malley, 2020) so as to enable them prepare lectures in the context of online classes (Makoni, 2020). To mitigate this, the Commonwealth of Learning (COL, 2020) has developed the "Guidelines on Distance Education during COVID-19" to help governments, educational institutions, regulatory agencies, parents, and students to effectively deal with this crisis so that no one is left behind. Furthermore, COL has initiated several joint activities aimed at building the capacity of staff in distance and online provision and harnessing the potential of Open Educational Resources (OERs) to offer quality content. Other plans could include developing a comprehensive remote education policy, instituting strategies to incorporate critical aspects of the COVID-19 experience in Education Management Information System (EMIS) to inform education sector reform, and leveraging the lessons learned from the successful and failed partnerships and collaborations during the COVID-19 crisis to improve future stakeholder engagement in times of crisis (ADEA, 2020).

There has been an exponential increase in global research efforts to understand and control the virus (The Economist, 2020b), and some journals in the aforementioned disciplines have started to fast-track the peer-review process to accelerate the publication process (The Economist, 2020a). While under normal circumstances, publishing in scientific journals usually takes years, speed has become paramount and journals "have squeezed their normal processes down to days or weeks" (The Economist, 2020b, n.p.), thus providing physicians, policymakers, HEIs, and heads of state with the latest science in order to make far-reaching decisions (The Economist, 2020b). Other journals have lowered their paywalls to make research about SARS-CoV-2 more widely available (The Economist, 2020a).

The relative dearth of systematic and macro-level research has led to the exploration of creating a database that shares the research on higher education openly, such as the "COVID-19 in Higher Education Literature Database (CHELD) V1.0." This database makes the access to timely knowledge easier, with an aim to promote knowledge-sharing behaviors in higher education providers during the pandemic (Butler-Henderson et al., 2020). Now, there is need for university leaders, telecommunications companies, global employers and students to come together to develop a common agenda for the future of digital higher education (Waruru, 2020a).

The financial resources can be a critical component in handling and recovering from acute crises (De Carvalho et al., 2016). Additional financial support to the education sector for managing the disruption caused by the COVID-19 pandemic has largely been from the national stimulus or special funds as well as from external sources, particularly from major international and regional development organizations such as the World Bank Group, the African Development Bank Group, and the Global Partnership for Education, among others. A major gap exists, however, in financing and sustaining a solid mechanism for the education sector in Africa to manage crises like COVID-19 and to guide remote education on a mid-to long-term perspective. Availability of emergency relief funds in the form of soft loans or private donations will help students with daily expenses in order to continue their studies.

In an unprecedented situation as a result of COVID-19 pandemic, social support system may provide a valuable relief to those severely affected by the crisis (Abdullah et al., 2020). Some of those affected groups may require psychological help or counseling in order to relieve them from mental or emotional crisis that may lead to severe stress and depression. It is particularly important for various parties involved in the crisis to react resiliently and develop suitable solutions to overcome the undesired situation. Stress in teaching online using technology (or technostress) is stress caused by the use of ICT (Christian et al., 2020). Accordingly, Sawalha (2015) has called for an organizational culture which is open, trustful, and learning-oriented.

Conclusion and lessons learned

According to Giordani and Rullani (2020) the world lasts three periods: period one is to be interpreted as the pre-COVID phase; period two in which the COVID-19 shock occurs, and the non-digital market temporarily disappears; and period three is intended as the post-COVID era. COVID-19 has revealed that healthcare and public health systems were unprepared to meet a pandemic challenge due to underfunding, poor supply chain access, and disregard for healthcare personnel, school nurses included. During the pandemic, the things we all took for granted no longer became an option. Education is encountering the greatest disruption, marking a radical departure from historical modes of delivery. Whereas distance education is often touted for reasons such as geographical isolation, disability and wars, it is now being used as a tool for dealing with a medical tragedy (Al Lily et al., 2020).

Although there is a positive move in using new online and offline learning tools, platforms, and materials, it benefits only a small proportion of the learner population (ADEA, 2017; Oyedotun, 2020). The sudden transition to online pedagogy as a result of COVID-19 in developing countries has exposed some inequalities and challenges, as well as benefits. These challenges and inequalities have now become the new realities in the educational sector of developing countries. Adapting to the changes in the education

sector could benefit HEIs and staff in the long run; for instance once COVID disappears, the online provision will stay and be a solid element of teaching and learning (Siwinski and Bilanow, 2020). Online technology will not only change the teaching process and make it more competitive (for lecturers), but as a disruptive force will create opportunity to accelerate profound changes in the organization and introduction of innovation. There is, therefore, need to rethink how to deliver quality education equitably and inclusively, and the role of technology as one of the key enablers.

Introduction

Knowledge is tied to power (Foucault, 1977/1995). The power to produce, disseminate, and legitimize it looms large. Although knowledge can be produced anywhere by anyone, the nexus of power relations in society, acting as a gatekeeper in the interest of maintaining control, determines what is accepted and the truth (Foucault, 1980; Gramsci, 1971). Hence, the production and use of knowledge is ultimately linked to the nexus of what Foucault called power/knowledge. Foucault emphasizes that power is reinforced and maintained through acceptance of certain forms of knowledge and truths (Rainbow, 1991). This interlinks between power and knowledge has dominated our understanding of what constitutes legitimate knowledge production and utilization.

Historically, Eurocentric perspectives and narratives have dominated knowledge production. “The ‘Western university’ and intellectual property regimes were not initially built for all thinkers and knowers, nor for inclusive human advancement” (Wilder, 2013). These traditional, presiding forms of knowledge have worked to exclude other forms of knowledge with worldviews that differ from those in dominant cultures. These exclusions often censored knowledge originating from the Global South and indigenous cultures. By shutting out voices from the Global South, perhaps unwittingly, knowledge production enters the contested space of power and epistemology, and the enduring legacy of colonialism. Traditional academic perspectives reflect European and American knowledge hierarchies. Bhambra (2014) examines how decolonial thinking has the “radical potential” to force us to rethink traditional forms of knowledge production. In thinking about that “radical potential,” Bhambra (2014) writes, “Postcolonialism and decoloniality are only made necessary as a consequence of the depredations of colonialism, but in their intellectual resistance to associated forms of epistemological dominance they offer more than simple opposition. They offer, in the words of María Lugones, the possibility of a new geopolitics of knowledge” (p. 120).

Over the last decades, the way knowledge is generated and circulated has been transformed. It is our responsibility to understand how those changes have enabled other forms of knowledge to become more accessible and thus, easier to render visible. However, in some instances these changes made non-mainstream knowledge invisible, denying access to alternative world views. We offer a critical perspective of how knowledge is created and deployed with the ultimate goal to give voice to the voiceless and form to the unseen.

This review examines 5 topics associated with the production, use and privileges of traditionally accepted forms of knowledge. First, we review how knowledge circulates in higher education and how whiteness has dominated academic perspectives and knowledge. After understanding how knowledge has traditionally been circulated in academia, we turn to knowledge from the Global South in order to better understand the relevance of locality. Next, we consider how Indigenous forms of knowledge have been devalued over time and the relationship between imperialism, colonialism and knowledge. From there, we explore the democratization of knowledge and delve into how the emergence of the digital age has taken the democratization of knowledge further than at any time before. Lastly, we discuss practitioner knowledge, which has been consistently disregarded in favor of so-called “expert,” or traditionally legitimized forms of knowledge.

Academic perspectives

Delgado Bernal and Villalpando (2002) argue there is an “apartheid of knowledge” in the context of higher education in the United States. This phenomenon is maintained through what Scheurich and Young (1997) describe as epistemological racism that legitimizes Western ways of knowing in the academia and limits the possibility of non-Western (non-white) epistemologies from being considered a part of the mainstream research community. This means research produced by scholars of color that utilize theoretical

frameworks and methodologies different from established positivist traditions, is considered deficient, biased, and non-rigorous (Delgado Bernal and Villalpando, 2002; Solórzano and Yosso, 2002).

Patton (2016) insists we look at the composition of faculty members in the US in order to better understand how/why certain perspectives are dominant. She argues the lack of diversity in higher education is commonplace. According to the Pew Research Center, faculty members, despite the racial and ethnic changes in the past two decades, continue to be majority white; the Center notes that white faculty members make up about 76% of all college and university faculty members compared to 55% of total undergraduate students. Conversely, they found Latino, Black/African Americans, and Asians make up only 5%, 6%, and 11% of faculty members, respectively. Further, it is important to note that faculty of color are more likely than white faculty to be in non-tenured, lower, and lesser prestigious academic ranks such as lecturers and/or instructors; be concentrated in institutions of lesser prestige and with fewer resources; and be in departments that are considered less prominent and prestigious within higher education, namely the humanities, social sciences, ethnic studies, women's studies, and education (Astin et al., 1997; Garza, 1993; Allen et al., 2000). Garza (1993) describes these patterns as the "ghettoization" and "barrioization" of faculty of color and their scholarship.

Scholarship produced by scholars of color is often dismissed, marginalized, footnoted, or unacknowledged (Delgado Bernal and Villalpando, 2002). Stanley (2007) notes many publishing and journal editorial boards continue to favor mainstream research. While presumed to be fair and impartial, this process in fact erects barriers that reify, privilege, and confer status only to knowledge which has been legitimized or formalized by the academy. The ultimate result is to reproduce an incestuous cycle within higher education where a "small group of White faculty repeatedly cite their own work contributing to their status" (Patton, 2016). All of which results in "opportunity hoarding" and the concentration of power for white faculty. Faculty of color have limited status, tenure rates, and "voice." As Trinh (1989) reminds us, too often the only way to "science" is through whiteness; colonized and subjugated knowledge struggles to be seen as legitimate outside Western interpretation, analysis, and mastery. Ultimately, knowledge legitimized through the academy falsely normalizes the way(s) of knowing and knowledge created and imposed by colonizers. Dominant white, Western, and Global North world views, about what is legitimate knowledge, permeate every institutional structure, policy, and practice to sustain the status quo in higher education (Sefa Dei, 1999).

Global South perspectives

Current knowledge is framed and communicated through a Western, Global North lens. UNESCO's Global Education Coalition (GEC) is a timely initiative for an era of ever-increasing conflicts, xenophobia, and other forms of discrimination. However, it has encountered difficulty in gaining traction in some parts of the globe. This difficulty in local relevance is, in no small measure, due to its narrow definition of values and principles. Put simply, GEC lacks adaptability to local realities because it marginalizes important principles, values and world views of Global South societies. Perhaps the most conspicuous omission is the absence of voices from the Global South and the failure to connect important key concepts such as *citizenship*, *human rights*, *democracy*, and *peace*, (highly political terms) to localized concepts and values. Moreover, the framework for GEC is based largely on documents that, while globally ratified, are still locally controversial, such as the "Universal Declaration of Human Rights" and "the World Programme for Human Rights Education" (UNESCO, n.d.).

By overlooking important voices on its central issues from the Global South, GEC unwittingly enters the contested spaces of power, epistemology, and the enduring legacy of colonialism. Post-colonial scholar Boaventura de Sousa Santos defines colonialism as "a system of naturalizing differences in such a way that the hierarchies that justify domination and oppression are considered the product of the inferiority of certain peoples and not the cause of their so-called inferiority" (de Souza Santos, 2017, p. 18). In addition to realigning global paradigms of power and legitimacy, colonialism was also complicit in what Sousa Santos calls epistemicide "the destruction of the knowledge and cultures of [oppressed] populations, of their memories and ancestral links and their manner of relating to others and to nature" (de Souza Santos, 2017). Given this history and the continuing imposition of external agendas in the post-colonial era, societies in the Global South are justifiably suspicious and apprehensive of "international" initiatives that lack connection, relevance, and alignment with local realities and national priorities.

The goals and objectives of GEC, along with its resource documents, are largely communicated and conceptualized through a Global North lens—specifically a Western worldview. Although there are universally accepted and acknowledged ideals, one encounters difficulties in interpretation and placement of these universal ideals in local context. GEC appears to have overlooked the fact that the echoes of history and geopolitical alignments are a constant restraint in the effort to reach a consensus on workable, universal definitions of ideals, values, and goals. An illustration of this difficult task is evident in the titles of GEC resources offered by UNESCO with titles containing words such as "prevention of violent extremism," "reinforcing human rights," and "countering radicalization" (UNESCO, n.d.). The underlying intention of these resource packs is the near universal agreement on the need to protect civilians and to recognize dangerous viewpoints that lead to violence. However, the global and local divide on the understanding of these concepts is conditional on terminology and political outlook. Utilizing politically sensitive terms like "extremism" can be more detrimental than helpful to the GEC's purposes in developing these materials (Appiah-Mensah, 2007).

Creating resonance at the local level, requires first, deconstructing the primary concepts of GEC, followed by consciously contextualizing and incorporating epistemologies of the Global South. Key to this deconstructing and localizing is recognizing that by stating that these values need to be 'instilled' in a member of any given society, and in the process offering an externally formed definition for these values, GEC is implying that these humanistic values are locally absent.

Moreover, GEC is laden with politically charged terms such as citizenship and human rights that are strictly circumscribed, inhabiting adaptation to local equivalence concepts which may facilitate incorporation into the curriculum. For instance, although GEC may define citizenship in broad terms such as individual expression, creativity, and awareness. For a large part of the world, citizenship is a concept that encompasses contradictions, such as “belonging vs. exclusion,” “granting of rights vs. denying rights,” and “access vs. expulsion.” Additionally, it is important to develop a historical understanding of how these values and ideals were developed. For example, the current understanding of Human Rights results from reinterpretation of previous European colonial standards of who is “civilized” to one, which sees the US as Western civilization ideal. Hence, Human Rights standards are “universal” only inasmuch as these are a barometer for civilization and who is defined as civilized-as confirmed by the prevailing power championing the diffusion of these ideals and standards (Mignolo, 2012, p. 296).

For GEC to resonate locally, it must first accommodate Global South perspectives and secondly, reject imposition of its overly prescriptive language, concepts, values, and ideals and thirdly, allow for local interpretation and incorporation. For instance, the stark contrast in the discourse on colonialism and post-colonial era illustrates the fissure in perspective and interpretation between the Global North and South, as well as the compartmentalization of non-Western academics and authors. Works of Global South academics and authors such as Said (1979a), Rodney (1974), Fanon (1961), and Achebe (1960), that offer the intimate, personal, and social impact of oppression and offer contextualized interpretations are often framed as niche and regulated to specialized courses. Meanwhile, the canons are such works as Conrad (1996), Herskovits (1938, 1941, 2006), Forster (2005), and Coleman (1955, 1971, 1995), which are drafted through a Eurocentric lens and at times perpetuate Western superiority and ideology. This disparity in legitimacy and the detraction from the locally centered narrative for an established flawed Global narrative aptly illustrates the shortcomings of not only the GEC but also the wider academic and political discourse. As witnessed numerous times in history, the Global is ill equipped to define the priorities and conditions of the local because as Edward Said (1979) warned in *Orientalism*, “cultures, and histories cannot seriously be understood or studied without their force, or more precisely their configurations of power” (Said, 1979b, p. 5).

Indigenous knowledge(s)

Indigenous knowledge has been defined as “the foundation of Indigenous governance, ecological stewardship, social, ethical, linguistic, spiritual, medical, food, and economic systems, so that the continual production and reproduction of local, land-based knowledge is the basis of Indigenous identity and sense of place in the world, as well as of Indigenous groups’ very survival as distinct peoples” (Grey, 2014). Arguably more important than Indigenous Knowledge (IK) functioning as a survival mechanism, is its power to help free Indigenous people from the constraints of colonial rule and thought. In discussing the impact of Indigenous Knowledge for indigenous peoples, Simpson (2004) writes, “Recovering and maintaining Indigenous worldviews, philosophies, and ways of knowing and applying those teachings in a contemporary context represents a web of liberation strategies Indigenous Peoples can employ to disentangle themselves from the oppressive control of colonizing state governments”. Furthermore, Bruchac (2014) notes that those from outside Indigenous communities trying to understand indigenous knowledge should always consult with “local indigenous knowledge-bearers” to ensure accuracy, ethical practice, and avoid unnecessary harm.

The methods we use also have power in the construction of knowledge. Patel’s (2016) *Decolonizing Educational Research* explores the ways in which colonialism seeps into modern processes of knowledge formation and educational research. In “Educational Research as a Site of Coloniality,” Patel states:

Education research, through both meaning and matter, has played a deleterious role in perpetuating and refreshing colonial relationships among people, practices, and land. This is not to say this is the only purpose that educational research has performed, nor that all educational researchers are colonizers themselves. Rather, it means that logics of coloniality, which are connected to property and stratifications of society, are problematically enlivened through educational research (p. 12).

By turning to Indigenous knowledge, we can be equipped to understand something free of the colonial perspective—an imbalanced and miss referenced partial view. The lack of exposure to Indigenous knowledge in higher education and journals works to reproduce colonial logics and confer status to Western epistemologies. This absence renders Indigenous knowledge and cultures invisible. In addition to research’s potential to refresh colonial logics and render certain realities invisible, Patel (2016) also explores the difference in temporarily improving experiences versus systematically addressing and understanding them. She argues that, “When educational research focuses on these strata without addressing the societal design that creates the strata, it becomes complicit in the larger project. It may temporarily improve a small set of experiences, often conceptualized with gaining footholds on a slanted wall, rather than reconsidering the entire structure” (p. 18). Indigenous knowledge has been threatened by assimilation, industrialization, and outmigration. Furthermore, Grey (2014) states that “massive depopulation due to epidemics and malnutrition, immediately upon and for hundreds of years following the arrival of colonial powers in traditional territories, resulted in an incalculable loss of Indigenous knowledge” (p. 3231).

Democratization of knowledge

The emergence of the digital age has taken the democratization of knowledge further than at any time before. The invention of the printing press advanced the dissemination of knowledge not only to the broader populace but also faster than in previous eras. Similarly, digital technology has not only propelled knowledge further but has also democratized the creation of knowledge. Today, the proliferation of digital platforms has transformed how we create, disseminate, and legitimize knowledge. Not only has it increased the speed and spread of knowledge and information, it has also raised questions of who is an “expert” and qualified to produce knowledge challenging traditional epistemology.

The democratization of knowledge occurs through inclusivity and diversity in the production and dissemination of knowledge. The dominance of European perspectives and prevalence of “gatekeeping” have been, and continue to be, significant barriers to broadening representation in knowledge production and dissemination. However, the Internet and technological innovation have forever altered the landscape and created a platform to challenge traditional epistemology.

The Internet has launched a significant global revolution in knowledge production and access. Today digital technology is present in all aspects of knowledge production, from instruction to collaboration to publishing to research (Altbach et al., 2009). For instance, EdTech, which is at the intersection of technology and education, integrates innovations and advances in technology to support, supplement, customize, personalize, and diversify learning (EdTech 2.0, 2017). Innovations in EdTech gave rise to online learning, which employs computers and the Internet as a delivery mechanism for courses and instruction (Moore, 2013). With each stage of innovation, the goal has been to create a learning environment that diminishes the distance between instructor and student as well as the student and the material. Digital innovations have expanded EdTech from simple computers to interactive displays and simulations, increasing interaction between instructor and learner (EdTech Review, 2013). Although access to both the Internet and knowledge dissemination channels has improved, equity remains elusive with non-western countries facing significant connectivity challenges, which has implications for fully leveraging technology in education. However, with concerted efforts to increase affordability and access, EdTech can potentially expand learning, collaboration, and research, thus amplifying underrepresented voices and eventually diversifying epistemology.

College and university research libraries have been the most significant beneficiaries of digital technology innovation. Libraries no longer just curate books and materials for those who physically enter the space. They support e-learning students and provide mobility for digitally accessing materials and services. The digital age college library is both digital and physical, where students can check out a book or access it online from their personal computers. Beyond curating books and materials, it has become a hub for training and education on innovative technology, from coding to data management tools that support learning and research. Libraries are places where students go to access multimedia materials, high-tech solutions such as 3-D printers and laser cutters, and data visualization walls.

An example of a new era of libraries made possible by leveraging technology is the HathiTrust Digital Library, a digital repository collaborative of research libraries across the US, Canada, and Europe. Although a “library”, the HTD has no physical space or collection. It only has a digital presence, and all its resources are located online and managed by its member libraries. HTD increased digital access to books that were once in limited collections. It currently houses 17 million digitized volumes, 95% scanned by Google, that exist entirely online. All 9.5 billion pages are indexed with metadata for each volume and shared across partner universities. The breadth of its digital collections allowed the library’s research center to create the *Bookworm Visualization Tool* that “explores the evolution of words over time; an *Extracted Features Dataset* that tallies up words and parts of speech” (Bookworm Project, n.d.). These innovative research tools utilize AI to compare and learn patterns and provide new data and approaches to analysis, critical support, and resources for researchers.

The abovementioned instances highlight the progress in accessing existing knowledge owing to technological advancements. However, technology has also altered a critical component in the democratization of knowledge, such as the revolution in the legitimization of knowledge (Isife and Nneka, 2016). Although still fraught with challenges, the abundance and breadth of information available on the Internet through various platforms weakens the hold of “gatekeepers” as “we are all equally authoritative with respect to any issue” (Kitcher, 2017, p. 3). The reliance on “expert” opinions or select groups no longer holds sway when individuals become “cognitively more autonomous” by filtering and processing the vast array of information available on the Internet (Kitcher, 2017, p. 3). Though in some cases this leads to acceptance of misinformation, broad access to diverse knowledge and information is ultimately a net benefit for society and democracy.

Practitioner’s knowledge

Again, it is important to ask ourselves, “who produces knowledge?” Much of our current knowledge is obtained by way of some sort of empirical research process. Whether a case study, longitudinal survey, demographic analysis, or experiment, the research, and therefore knowledge we have unceasingly validated, is often linked to something that can be observed and measured. So, what happens when other forms of knowledge that do not follow conventional frames arise?

Practitioners’ knowledge values the knowledge that already exists within people and communities. With concern for the undervaluing of practitioner knowledge within studies of student success, Bensimon (2007) writes “When I say that practitioners are missing, I am referring to the lack of scholarly and practical attention toward understanding how the practitioner—her knowledge, beliefs, experiences, education, sense of self-efficacy, etc.—affects how students experience their education.” She is concerned that

the knowledge that lives within faculty, that they gained over the years is overlooked. Bensimon (2007) goes on to discuss how “practitioners for the most part are likely not aware of what knowledge or experiences constitute their sense-making and how the judgments they make about a phenomenon [...] are shaped by that sense-making (p. 446). In other words, the knowledge that lives within practitioner’s may not always be visible to the practitioner themselves, and it is therefore imperative that we empower practitioners to locate that knowledge within themselves.

The Capacity Building Center at UCLA recognizes the importance of practitioner knowledge and is utilizing it in one of our current projects (<https://www.uclacbc.gseis.ucla.edu/>). The Capacity Assessment Platform (CAP) is a diagnostic instrument administered through a consultative process to evaluate academic, administrative, and service operations of educational institutions. CAP is designed to support data-driven capacity building in areas such as management, processes, teaching, research, and student and faculty services. The tool consists of quantitative and qualitative approaches to develop a complete appraisal of the institutions and identify areas for improvement and intervention. We emphasize participatory processes and targeted investments that contribute to the development and sustainability of institutions, communities, and nations. In aligning with the value of practitioner knowledge, we aim to consciously promote culturally sensitive innovation and help advance local solutions to local problems expressed by those affected by the problems.

Our evaluations are meant to help identify and improve areas within institutions, with the input of the practitioners of that institution. It is critical for us that at each level of assessment, we are communicating with people from that institution who can provide context for initial findings and share their understanding of the assessment. This project largely relies on improving practice that is already in place. We intend to help show the value and importance of practitioner’s knowledge through our process and evaluation. The project is collaborative and demands a constant line of communication between both parties. This evaluation centers the knowledge of the practitioners at the institution to implement the strategies that would make most sense for their university. This is not only important for longevity of projects, but because it gives power back to the people being “studied.”

Conclusion

Knowledge is inextricably linked to power and wealth. Historically, Eurocentric worldviews, narratives, and priorities have controlled the production, dissemination, and validation of knowledge. By excluding voices and perspectives from the largely non-white, Global South, Eurocentric production/dissemination/utilization of knowledge enters the contested space of power, epistemology, and the enduring legacy of imperialism.

We offer a critical perspective on how knowledge is generated and deployed; by who and to what ends? We examine knowledge in higher education; knowledge in the Global South; devaluation of Indigenous knowledge; democratization of knowledge production/access in the digital age; and the importance of “Practitioner knowledge” alongside “Expert knowledge.” Our larger goal is to challenge and correct established hierarchies for the production and utilization of knowledge. Ultimately, the quest for knowledge-and effective applications to improve our lives- is best served by approaches that maximize diversity and inclusion and that empower “numerous voices at the table.”

History of research funding in higher education

Higher education institutions have evolved substantially over the last century with significant advancements in funding in the last several decades. Grant funding in higher education is often used to implement projects and support innovative research. The demand for higher education increased during the 1940s through the 1960s and pushed university systems to enhance knowledge production through the development of research centers and programs. Higher education enrollment is linked to a variety of advances including economic growth, social development, and political stability across the world (Buckner and Khoramshahi, 2021).

The demand for research funding has increased alongside the demand for public education leading to a greater supply of funding from public and private entities. Federal government spending toward research has increased since World War II (Benner and Sandström, 2000). During the last 50 years, the increase in funding led to a rise in the number of published articles, issued patents and faculty member salaries (Payne and Siow, 2003). Federal governments are often incentivized to provide grants to stimulate economic growth, advance prosperity and wealth, improve social and economic wellbeing, fund ground-breaking research, and maintain a competitive global advantage. Total funding has increased substantially across countries since the middle of the nineteenth century (Aagaard et al., 2019).

Over time, investments in higher education research have driven broader economic development and progress at the local, state and national levels (Atkinson and Stewart, 2011). Grants generally fund a variety of social justice, law enforcement, social services, and health/medical initiatives. Gains in scientific discoveries and research achieve national objectives to drive economic growth. Universities are able to conduct early-stage research which can promote long run scientific development which the private sector typically draws on for ideas and innovation for the greater public.

Over the last two decades research and development as a percentage of GDP has doubled in the world's wealthiest countries (Bloch and Sørensen, 2015). In order to maintain an advantage in a globalized economy, countries rely on universities to create and disseminate knowledge to the greater public (Himanen et al., 2009). Research performed at universities is essential to supporting production within the private sector. Over the last three decades, as private corporations have had to close down research laboratories, US universities have driven American global innovation and leadership. Grants to higher education institutions play a critical role in funding public and private service projects and discoveries that have a broad impact on global economic competitiveness.

Research and Development funding to higher education institutions in the United States has led to significant technological and communication advancements, positioning the United States as a global leader (Singer, 2014; Ulferts et al., 2021). The US has invested over \$53 billion in academic science research in recent times accounting for nearly 60% of total research funding to universities (Lanahan et al., 2016; Payne, 2001). A large portion of federal spending in the United States has been geared toward higher education grants since the late 1970s. From 2000 to 2005 the annual mean size of awards from the National Science Foundation has increased by 41% (Wagner and Alexander, 2013).

Theory and the distribution of funding models in higher education

In recent times, universities rely on financial incentives to promote research development. A large number of public and private entities provide grants each year. In the United States the Bill and Melinda Gates Foundation, the Ford Foundation, the Andrew W. Mellon Foundation, the Spencer Foundation, and the National Science Foundation are some of the top organizations and programs providing grant support. The development of these organizations in the United States and similar organizations abroad are tied to important theories around economic growth and research and development capacity. Postwar research conceptualized the relationship between research funding in higher education and innovation outcomes (Szarowská, 2017).

The Solow-Swan model argues that economic growth and industrial expansion requires up-to-date technological advances in research (Guerrini, 2006). From this conceptual framework, capital growth, labor growth, and productivity all operate according to levels of technological progress. According to the Solow-Swan model, research and development funding is central to economic policy. Studies have found that research and development expenditures were correlated with economic growth in both the United States and the European Union during the 1990s and early 2000s. Global GDP growth then reflects the adoption of new technological ideas and the diffusion of technological change across borders.

Several important funding theories outline the role of funding models in research and the relationship between higher education research and state agendas (Himanen et al., 2009). Some scholarship argues that in the context of higher education, two dichotomous models of state steering occur. The relationship between the state and higher education funding is either tightly or loosely linked (Gornitzka and Maassen, 2000; Neave and Vught, 1991). Other findings suggest that in order to compare and analyze how the funding relationship between states and universities shifts over time, additional models of steering relationships are necessary. During the late 1980s Olsen theorized that four models including the sovereign state, institutional state, corporate-pluralist state, and classical liberal state/state supermarket model more accurately described the ever-changing relationship between the state and the university (Olsen, 1988).

The sovereign state model suggests that higher education is an instrument that the national government uses to achieve broad political, economic or social goals. In contrast, the institutional steering model follows that universities exercise autonomy and must protect academic findings and traditions so that higher education institutions are not at the whim of national governments. The corporate-pluralist model seeks to recognize the multiple stakeholders that exercise authority and control in higher education including faculty, staff, and students. Lastly, the classical liberal state or supermarket steering model follows that the state plays a relatively minimal role in higher education and that the primary objective of the university is to conduct teaching and research.

More recent theory points to differences in the allocation of research funding based on specific characteristics of the research. Theory suggests that the properties of funding arrangements either discourage or promote different types of research (Laudel and Gläser, 2014). Researchers' practices of producing new knowledge depend on the political and governmental conditions for research. The epistemic and institutional properties of research projects shift depending on funding parameters. Laudel and Gläser (2014) find that relational properties, particularly the planned impact of the research project and the local properties of the individual characteristics of the project work together to alter the chances that a project receives grant funding. Research funding in higher education is dependent on the match between the epistemic properties of the research and the institutional conditions under which funding can be made. Research and development expenditures are also tied to conceptions of economic growth and the relationship between higher education institutions and the state.

Higher education funding across countries

The global context of research and development is central to understanding regimes of higher education funding. A substantial majority of research on funding regimes has centered on the US and Canada and parts of Europe. In countries outside of the United States, particularly countries in Europe, research and development expenditures have grown significantly. For example, universities in the UK and Finland have had some of the most competitive research funding environments (Auranen and Nieminen, 2010). Research has also become more highly regulated across countries outside of the United States. For instance, the British government evaluates university research to ensure an equitable distribution of support. In this case, research funding is allocated at the national level according to numbers of faculty and students. In other countries like Australia, Norway and Finland, there are fewer regulations and more incentives for universities to compete for funding (Auranen and Nieminen, 2010).

Countries outside of the United States have increased their commitment to funding scientific development. In the United States, funding is at the discretion of Congress and in recent years the United States has faced challenges with meeting federal funding needs (Atkinson and Stewart, 2011). Decreases in funding at the federal level in the United States may have indirect consequences on research investments from non-federal sources. In other contexts, like China for instance, research funding makes up a larger share of GDP growth at 59% (Atkinson and Stewart, 2011). China has become a leader in research and development based on the number of scientists engaged in research and the level of investment (Boeing, 2016). Similarly, Korea, Ireland, and the UK all increased research funding amounts over 30%, nearly double the rate of research funding growth in the United States (Atkinson and Stewart, 2011). In the UK two-thirds of private sector productivity during the early 2000s can be attributed to innovation in higher education. Australia and Norway for instance have seen a steady increase in state funding for research and development since the 1990s. The United States' decrease in funding from the federal government risks American global competitiveness in the long run (Atkinson and Foote, 2019). Other developed and developing countries invest a larger percentage of GDP in university research leading to more innovation-based jobs and larger economic returns. In fact, western European countries have consistently ranked among the top ten countries in terms of research and development spending (Dvouletý et al., 2020).

Funding agencies across countries also vary in the evaluation criteria used to determine the potential of scientific research and the allocation of large and small grants. Some national funding agencies emphasize societal relevance and broader implications, as is the case in Australia, Canada, France, Portugal, Netherlands, UK, and the United States (Meirmans et al., 2019). In these countries funding agencies require researchers to translate the science to the public policy arena. In other countries like Switzerland, Germany, and Sweden the emphasis on the societal impact is less necessary and rarely required. Funding distribution also varies across countries. For example, France, parts of the UK, Switzerland, Australia, and Norway often provide research to large teams of researchers

rather than individuals (Lewis and Ross, 2011). In contrast Canada, Germany, and the Netherlands provide grants to individual-led projects often in which a single applicant is preferred (Meirmans et al., 2019).

Despite important differences in allocation and broader research impact, countries across the world similarly provide grant funding that lasts for one to five years with most countries also accommodating flexibility in budget allocations. Countries across Europe and the United States also typically review grant proposals using a panel of experts over one or two rounds of review. In most countries, the panel includes external reviewers in addition to a panel of experts. Applications are also similarly judged and evaluated across countries. Evaluations typically focus on the quality of the project and of the researcher or research team. Some countries look at the novelty of the research like in Sweden, or the track record of the researcher like in Switzerland.

There is substantial variation in the expected length and structure of grant proposals across countries which creates different administrative burdens for researchers and research teams. In Australia, France, Portugal, and the United States, the burden to submit a proposal is fairly high with proposals averaging near 20–25 pages with some countries involving multiple rounds of evaluation (Meirmans et al., 2019). Funding agencies across countries also vary in their funding of diverse and mobile projects. Some funding agencies like those in Switzerland, Germany, and Sweden provide funding for use outside of the home country. In contrast, nations like the United States, France, and Australia encourage within-country research. Differences in mobility allowances can significantly shape scientific breakthroughs and discoveries as research advances when disciplines are crossed and when a variety of international experience can be combined. Overall important variation exists in how governments allocate funding and how researchers gain access to funding.

Trends in research funding and current challenges

Several trends over the last two decades have influenced funding at the university level. Universities have developed an increasing number of centers and large programs that are supported by large-scale project grants (Bloch and Sørensen, 2015). Over the last three decades research funding models have shifted from block funding for universities toward project funding arrangements (Lepori et al., 2007). The shift in funding toward centers has meant that a greater share of research funds is concentrated among a smaller number of researchers within a given center (Bloch and Sørensen, 2015). The project funding arrangement has implications for the organization of research and has increased the level of authority that university management teams and research group leaders have relative to individual scholars. Rather than supporting individual projects, grants are now more cooperative, supporting a number of researchers under the same center (Bozeman and Boardman, 2003).

Another important trend has been the share of funding from federal and non-federal sources. Direct government funding often provides the core funding that is allocated to assist universities in maintaining the basic infrastructure necessary to perform research activities. Federal funding has made up a large part of this increase in funding nearing 60% of total funding given to universities in the United States during the 1990s (Hicks and Katz, 2011). In recent decades, the share of direct government funding has decreased especially in the United States, and the share of external funding, especially funding from private industries has increased (Auranen and Nieminen, 2010). Federal funding ensures that research investment from private corporations and non-profit organizations also increases. While academic institutions gain resources from a myriad of sources, federal investment plays an important role, so much so that decreases in federal research funding result in decreases in research investment from other private and non-profit sources (Muscio et al., 2013). In past decades, federal funding helped ensure larger research outputs but with recent decreases in federal funding, universities rely on private companies to make up the difference.

Research finds that federal funding crowds in investments from other private and industry sources (Lanahan et al., 2016). Federal funding is an important complement for additional investments. Although the impact of federal funding varies considerably depending on the academic discipline, the form of institutional control, and the capacity of the field research, federal dollars help bring in non-federal funding to achieve broader societal objectives. Federal and non-federal funders work in a complementary relationship to ensure the development of scientific knowledge and discovery. Federal investments help to advance national directives and drive economic expansion and non-federal investments drive commercial innovation and provide a broader societal benefit for non-profit organizations and local economies.

Government funding toward research seeks to promote research efficiency. Government funding is often broadly distributed to maximize economic development and to enhance diversity and participation in research (Hicks and Katz, 2011). In recent times, global competition has also pushed the concentration of research funding in the hopes of driving technological advancements over other countries. As funding becomes increasingly concentrated in the hands of a single researcher or a group of researchers, these individuals and teams gain a cumulative advantage in which each new success is leveraged based on past accomplishments.

Across countries, researchers with substantial early funding will continue to outperform researchers who did not have access to this earlier funding source. Continuing to reward past top research performers may limit the funding potential for future top research performers (Bloch and Sørensen, 2015). Instead of concentrating research funding, studies suggest that dispersal of funding can reduce cumulative advantages (Berg, 2012; Fang and Casadevall, 2016). A concentration of funding for a single individual or within a particular discipline or for a particular center may decrease the level of diversity that could be achieved if funding supported multiple smaller projects (Horta et al., 2008). This can be particularly detrimental for researchers in smaller countries who may narrow their disciplinary focus in line with specific research initiatives. In this case, rather than funding areas with the greatest potential, research funding is concentrated in a very specific field. Research concentration in this form can lead to more economic inefficiency (Bloch and Sørensen, 2015; Hicks and Katz, 2011; Mongeon et al., 2016; Nag et al., 2013; Sousa, 2008).

Arguments in favor of the concentration of research claim that research is more efficient once a critical mass of funding is obtained. Once a critical mass is reached, researchers have greater access to human resources, equipment, and infrastructure. Pooling of such resources can allow for the development of large-scale research projects that would be impossible without a large amount of funding. Under this premise, the resources contained within centers or under largescale research projects are necessary for promoting rigorous scientific research.

Evidence also suggests that grants of greater size also create more research visibility which can help communicate benefits to the greater public and create a more stable funding base. Concentrated funding is believed to promote researcher interaction and mutual learning and promote increased productivity (Lee and Bozeman, 2005). Under this arrangement resources are pooled to achieve greater strides in teaching and administration that would not be possible under individual grants. Fewer grants concentrated within a smaller number of centers may also result in a lessened administrative burden with fewer barriers for achieving scientific excellence (Bloch et al., 2016; Bloch and Sørensen, 2015; Breschi and Malerba, 2011; Hellström et al., 2018; Hicks and Katz, 2011).

While some studies favor research concentration, there is little evidence that increasing grant size necessarily leads to increased research output and productivity (Aagaard et al., 2019). Research also finds diminishing marginal returns as grant sizes increase above a certain threshold. Research output per researcher decreases even with increasing amounts of funding (Asonuma and Urata, 2015). As an example, while grant funding over time has led to increases in publications, recent research finds that funding success is only moderately associated with gains in publication and citation rates (Fedderke and Goldschmidt, 2015). Other research finds no association between the level of funding a center receives and research output (Gaughan and Bozeman, 2002). Across most studies, grant volume only slightly improves performance (Laudel, 2005).

Evidence suggests that an increased dispersal of funding has a positive impact on research productivity. For these reasons, findings tend to support a greater dispersal of research funding and a more efficient allocation of resources. Dispersal also ensures that knowledge is broadened and that there is greater research breadth (Fortin and Currie, 2013; Katz and Matter, 2017; Vaesen and Katzav, 2017). In contrast, a concentration of research funding can lead to greater marginal costs for researchers with diminishing marginal returns (Berg, 2012; Breschi and Malerba, 2011; Lorsch, 2015).

In this vein, a diverse allocation of research funding increases the chances of innovative breakthroughs (Fang and Casadevall, 2016). If research is spread across many individuals and multiple centers, then the chance for scientific developments increases. At the same time diversification of research funds also minimizes the risk that research funding is wasted. If one research group fails, more allocated funding could ensure that another researcher would meet success. Research funding dispersal also keeps students and researchers active and engaged in new developments. Allocated funding ensures that early and mid-career researchers are funded and that student researchers gain access to funding opportunities.

As funding sources have become more concentrated under large projects and centers, administrative burdens increase. Large grants must be appropriately managed and regulated and rather than focusing on research development, grant winners may be inundated with more bureaucratic requirements. Rather than promoting research innovation, researchers focus substantially more attention on grant fundraising and grant management (Alberts, 1985; Bloch and Sørensen, 2015). Large funding incentives also create significantly more competition which can in turn affect research productivity. For instance, a researcher competing regularly for funding may in fact spend more time and energy engaged in the grant writing process than in the research development process. Funding incentives can also unintentionally weaken the quality of research if the prestige of gaining quantitatively more grants outweighs the benefit of stronger research development (Butler, 2003; Langford et al., 2006). Overall, the allocation of research and development funding continues to be critical for the future of research productivity across higher education institutions.

Future implications in higher education grant funding

As research development and spending increases in countries outside of the United States, future research should center on country-specific and regional-specific evaluations of funding incentives and research productivity. To date, most studies of funding regimes center on North America, Europe, and Australia. Research funding is largely controlled by developed countries at the expense of developing countries (Harris, 2004; Kitzman et al., 2010). Global unequal relations of power constrain the research capabilities of developing countries. Future research should investigate methods for improving the potential research base in developing countries. Further, research collaborations should center on building and fostering scientific development in countries with fewer resources. Studies that examine global trends in research funding and that enhance the scientific capacity of developing countries will substantially enhance knowledge around research productivity. More research is needed to understand the funding models that countries use to allocate funding and how countries use federal and non-federal funding as investments.

Research funding in recent times faces challenges related to research concentration and inequality in grant dispersion. Future research should expand knowledge around funding concentration and how the size of grants shapes research performance and other outcome measures (Butler, 2010). Current research on funding concentration is fragmented and inconsistent. Future research should also investigate what a concentration of research funding means for gender and racial imbalances. Some research finds that an increased focus on large research grants in centers may exacerbate gender inequalities (Aksnes et al., 2012). Future research should determine how to distribute research funding more equitably to ascertain social and economic impacts and to address any adverse effects on equity. We currently have a limited understanding of the internal mechanisms and the external policies

that have resulted in the concentration of research funding. If evidence suggests that the concentration of funding can limit the diversity of research, then future research should determine how to best redistribute research funds.

Current evidence also suggests that public research and development funding has been declining over time. Future research should investigate comparative levels of federal and non-federal funding and trends over time. This strain of research might also suggest potential policy reforms that would ensure that government funding toward research and development is appropriately allocated. Private research and development funding is also an important area of future research. Future studies should determine the precise role of industry funding in higher education research and development.

In all, worldwide funding limitations still constrain the ability of federal and non-federal agencies to support scientific discovery. Future research is needed to ascertain the most effective way to allocate funding to support scientific exploration and to achieve the related economic and societal advances. Funding scarcity often creates unnecessary competition for limited research grants. Future studies should investigate and compare funding allocation practices and various approaches to the distribution of funding. Given that it is unlikely that available governmental resources will radically increase over time, funding agencies have the critical responsibility of determining the most efficient ways to allocate funding that will generate the greatest returns. Current research points to more funding allocation for small grants to multiple researchers and the funding of both center-based and individual-led projects. Allocation efficiency that produces positive outcomes may also improve if more long-term projects are funded, if there is more flexibility in funding schemes, and if there are reductions in the administrative burden of applying for funding.

As universities continue to rely on funding agencies for research support and as funding agencies grow, scholarship should continue to evaluate how social, economic, industrial and political interests are integrated into the evaluation and performance of research in higher education institutions. Performance-based systems have driven grant funding in the last decades and how performance measures are regulated will shape the future of research innovation and funding opportunities.

Given the COVID-19 impact of 2020 and the surge in research and development funding toward vaccine production, future research will need to assess short-term and long-term funding toward research development in other academic areas within higher education. The impact on research development spending is still unclear and policymakers and research funders are unsure of whether or not similar biomedical funding levels can be sustained in the long-term.

Overwhelming evidence demonstrates that investment in research and development is essential for productivity, growth, and innovation on a global scale. The loss of research and development infrastructure can have detrimental societal effects. Continued evaluations of research productivity and the impact of sustained long-term investments in research will be valuable for understanding future trends in scientific funding arrangements.

Introduction

The conditions for the exercise of institutional autonomy and academic freedom have improved in many African universities over the last two decades, since the eve of the 21st century. To a greater extent, these improvements have been an indirect outcome of the fiscal crisis of the state in Africa and the imposition of structural adjustment program (SAPs) in the 1980s and 1990s. Implementation of SAPs in the midst of a fiscal crisis was used as a carrot to persuade African countries undertake political and economic reforms, part of which required restructuring in the governance structures of universities in ways that made direct state involvement in the management of the institutions untenable. Politically, one party-governments that in the past undermined institutional autonomy and academic freedom in the universities gave way to multiparty governments, through constitutional reforms, with the new constitutions embracing a bill of rights, including academic freedom. Economically, the declining public funding to support universities forced governments to accord a greater degree of institutional autonomy to universities through the creation of new governance bodies that would allow universities greater latitude in generating own operational resources. Recent surveys on the state of academic freedom in the continent show that by 2016, 14 (25.45%) of the 55 African countries explicitly recognize academic freedom in their constitutions, 8 (12.7%) of the countries implicitly recognize the exercise of certain aspects of academic freedom, such as scientific research as a right in their constitutions, while the remaining 34 countries indirectly acknowledge the exercise of academic freedom in their constitutions (Kwadwo et al., 2016).

The constitutional provision and/or recognition of the right for the exercise of academic freedom does create an expectation that conditions for academics to exercise academic freedom largely prevail across the continent and within the institutions. However, recent surveys on the quality of academic freedom in the continent show mixed results, that tend towards an increasing abrogation of academic freedom, both directly and indirectly in most of the countries. The 2007 report by Education International, based on the EI barometer does suggest widespread limitation of academic freedom throughout the continent. Education International undertakes regular analyses of trends in human and trade union rights in the education sector across several issues, including academic freedom. The report shows that of the 50 African countries whose reports were analyzed, 15 (30%) cited no violations or existence of formal restrictions; 15 (30%) of countries had no formal restrictions but institutional practices which limited academic freedom were prevalent; 16 (32%) of countries had formal restrictions on academic freedom through widespread legislations; 1 (2%) had severe formal restrictions while 3 (6%) showed recent evidence of improvement in academic freedom (Educational International, 2007). Aggregating together the countries that had incidences of academic freedom violations despite no formal restrictions, with those that reported formal restrictions through legislation and those with severe cases would suggest that by 2007, violations to academic freedom was prevalent in 32 African countries (64%). This situation was attributed to the emergence of new challenges to the traditional ideal of academic freedom, coupled with new technologies, restructured traditional universities, an expanded private higher education sector that includes for-profit institutions, a privatized public higher education sector, and the emergence of corporatized research in the universities (Altbach, 2007: 7).

More recently, a March 2021 report by the Global Public Policy Institute and Scholars at Risk Network (Kinzelbach et al., 2021), does suggest that in a number of African countries new threats to academic freedom are emerging, while the old ones are still in existence, reflecting a largely a global trend. The report measures the degree of academic freedom using five indicators; freedom to research and teach; freedom of academic exchange and dissemination; institutional autonomy; campus integrity; and freedom of academic and cultural expression. Of the 44 countries whose data was available, 9 countries (20%) had an academic freedom index suggesting on average they were fully free. On the other hand, 13 (30%), 11 (25%), 5 (11%), and 6 (14%) were mostly free, moderately restricted, severely restricted and completely restricted (Kinzelbach et al., 2021). While these data does suggest some improvement, it also shows that in a majority of countries, some restrictions on academic freedom do exist despite the greater constitutional recognition.

Historical literature on academic freedom in Africa largely focuses on two indicators; the freedom of an academic to teach and undertake scientific work and the institutional autonomy to guarantee the right environment for teaching and research. Thinking of

academic freedom together with the other notions of intellectual social responsibility and institutional autonomy as issues that are supposed to co-exist simultaneously however switches the focus from external restraints to academic freedom and institutional autonomy to examining ways in which individual academics and institutions do in fact undermine academic freedom and institutional autonomy. In other words, academic freedom is only tenable when coupled with intellectual social responsibility and institutional autonomy, while institutional autonomy is justified if only to guarantee conditions for socially responsible intellectual engagements by academics. So, while in the past academic freedom was framed in the context of the relationship between universities and authoritarian states (Grimm and Saliba, 2017), this article will argue that the increased constitutional recognition of academic freedom at different dimensions and the yielding of the state to some degrees of institutional autonomy throughout Africa has not resulted to conditions for real academic freedom. Rather new challenges have emerged from within the institutions, and often with the culpability of the academics themselves, that have hollowed out the capacity of the institutions and the academics to exercise academic freedom and social responsibility. The management of the institutions and the academics have yielded the space vacated by the state to newer actors in the name of responding to new managerial imperatives in ways that raise new questions about the autonomy of academics and institutions from the new forces that claim to support the universities, at least financially. In the name of responding to the needs of industry for example, academic programs have been introduced with little input from academics while the participation of university senates and faculty in the academic affairs of the institutions have been limited to basic reporting and approval practices (Fulda et al., 2021). The trends accord academics little ownership of the academic issues of the institutions as would be expected in situations where real academic freedom and intellectual responsibility are exercised. The UNESCO (1998) declaration on academic freedom does emphasize a greater degree of self-governance by academics in matters to do with academic work and accountability by academics on the quality of research and teaching. The weakening of the oversight role of academics and university senates on the academic processes of the institutions does seem to have weakened the academic integrity of the institutions, with instances of academic fraud and poor quality of academic programs emerging as a major concern affecting universities across the continent, post-2000 (Zezeza, 2021).

The subsequent sections of this chapter draw from historical and contemporary analysis of trends in academic freedom and social responsibility in African universities, both in theory and practice. The article first discusses conceptions of academic freedom and its limited practice in African universities within the first two decades of independence. The second part discusses the contestations over academic freedom in the era of what has been referred to as “corporate” universities. Lastly the nature of academic freedom under new institutional governance structures and its implications are discussed.

Establishment of national universities in Africa and the quality of academic freedom in practice

The notion of academic freedom and the university as a space where such a freedom has to be exercised has remained problematic in Africa, at least at the conceptual level. Recent calls for the decolonization of aspects of university spaces and the content of courses points to this unfinished historical business. Although some literature does suggest that the establishment of national universities in Africa at the onset of independence heralded the era of contestations between the state and academics on issues academic freedom (African Watch, 1991), such literature presents a partial picture of what has been otherwise a complicated relationship. Academic freedom and what this would constitute in the African context remained problematic to the African political leadership even before independence. This is because the notion of academic freedom and the associated concepts of institutional autonomy and social responsibility derived from the package proposed by the Asquith commission for the establishment of universities in British colonial Africa of what would constitute a “university” then (Report of the Commission of Higher Education in the Colonies, 1945; Hargreaves, 1973). The Asquith Commission Report was clear that the envisaged university institutions to be established in the colonies needed to enjoy the same level of institutional autonomy and academic freedom similar to what existed then in British universities. The Report for example did recommended that academics in the new universities needed to focus on fundamental research devoid of any utilitarian considerations, and placed the obligations for providing the funding and sufficient climate within the institutions for the furtherance of these objectives on the governing bodies of the universities (Report of the Commission of Higher Education in the Colonies, 1945: 27). In practice however, especially regarding governance and the academic freedom of African staff, the new institutions lacked sufficient autonomy as either the secretary of state or the governor had more powers in appointing members of the governance bodies, with less representation from faculty members (Dlamini, 2002).

Between 1947 and 1970, universities were established in British colonial Africa, following the model proposed by the Asquith Commission, with, strong desire to preserve the traditions of academic freedom and institutional autonomy (Ashby and Anderson, 1966). The special relationship the universities had with the University of London influenced writing into the instruments for the constitution of the new universities’ frameworks meant to ensure autonomy of the institutions and the freedom of the academic communities, including the intellectual values of research, but exactly in the manner this obtained in British universities (Dlamini, 2002). Ashby and Anderson (1966) summarized the expectations of academic freedom and institutional autonomy to entail the freedom of academic staff to undertake the following functions without any external direction, but based on rules and traditions developed by the universities: the admission and examination of students, the development of curricula for courses of study, the appointment and tenure of office of academic staff, the allocation of income among the different categories of expenditure and the freedom of individual academics to teach according to their conscience and convictions and to publish views on their own subject or on any other subject permitted by law.

Though from time to time, transplanted notions of institutional autonomy and academic freedom and their suitability to Africa were questioned and cautioned (Hargreaves, 1973; Heron, 1964; Ashby and Anderson, 1966), these early conceptualizations have remained the pivot around which academic freedom and institutional autonomy have been invoked, demanded and defended. The entrenched government involvement in constituting the governance bodies of the institutions for example was copied by African governments at independence and would become the main contention on issues of academic freedom and institutional autonomy between academics and governments in the subsequent decades. The notions of academic freedom and institutional autonomy as framed then were not wholly agreed upon, especially by African academics in the new universities. There were those who thought academic freedom and institutional autonomy as framed then overlooked the context of the university in Africa, and were at most colonial importations of universal values and ideas into African institutions to serve the needs of the small expatriate staff at the expense of the needs of African institutions in the 20th century (Hargreaves, 1973).

Besides the issue of context, two other contentious issues arose during this period, and which would characterize contestations about academic freedom and institutional autonomy in Africa in the coming decades. The first was whether academic freedom would be secured in a context devoid of institutional autonomy, or if the reverse would be possible; autonomous institutions would trample on the academic freedom of academics (Ashby and Anderson, 1966; Crawford et al., 1967; Mamdani, 1993; Kori, 2016). The second issue was whether academic freedom was an absolute right that would be secured as an end or whether it had to be exercised only as a means to something greater; some form of academic responsibility to society (Ashby and Anderson, 1966; Hargreaves, 1973; Coleman, 1977; Crawford et al., 1967; Mamdani, 1993; Chachage, 2009).

Neither are the issues of political interference in the running of the universities that have been documented as largely responsible for the dysfunctions between state-university relations and the limitations of academic freedom a post-independence development. Literature documents the fact that in establishing universities in Africa during the colonial period, the colonial governments did allocate itself greater latitude in the governance and academic life of the institutions (Oloka-Onyango, 1992). In the case of Makerere university College, for example, The 1930 Makerere College Ordinance, the first legal instrument that set guidelines for the governance of the college provided for broad state control and regulation of the operations of the college by the Secretary of State through a chairperson appointed by the conference of East African Governors (Oloka-Onyango, 1992). A subsequent amendment to this ordinance passed in 1941 made the office of the Secretary of State central in the formulation of the terms of service, appointment and dismissal of members of the college staff, and gave the Secretary of State power to appoint and remove the principal of the college with recommendations from the Council of Governors (Oloka-Onyango, 1992). Needless to say, the situation in Makerere mirrored the kind of governance and academic structures that obtained in the other Asquith colleges. The literature that portrays governments in post-Independence Africa and their involvement in the governance of universities as the genesis of the abrogation of academic freedom and institutional autonomy in institutions that were otherwise devoid of a culture of political intrusion is not correct (See for example Sifuna, 1998; Munene, 1997). The situation represented more of a continuity such that in place of the secretary of State, presidents of the independent countries took over the power that had been bestowed on the Secretary of State and went ahead to populate the governing bodies with government appointees. It can be argued that in trying to take a steering role in directing the development and academic life of the universities, the political leadership in post-independence Africa were trying to follow a script laid out by the colonial administration that founded the universities. If the colonial government directed the nature of institutional life and academic freedom in the pursuance of the colonial project, the political leadership were in a sense following the same script in the pursuance of Africanization and national development.

Immediately after African countries gained independence, the political leadership started re-establishing the colonial universities into national institutions. Accompanying the nationalization of universities were attempts to have clarity on what a university meant within the African context and what the national expectations were from the perspectives of academic freedom and institutional autonomy. The political leadership looked upon universities and the few university graduates then available to help deliver the promises of independence. Academic freedom and institutional autonomy would only be invoked and granted only to the extent that it served the needs of “developmentalism” as articulated and understood by the political leaders. In the climate of “Africanization” of the time, the political leadership was in a sense seeking to enculturate both the university as an institution and academic freedom into an African context. African intellectuals and politicians had mobilized together in the struggle for independence under the banner of African nationalism and Pan-Africanism (Hyden, 1967; Mnguni, 1987; Mkandawire, 2002). The unity between the politicians and the intellectuals in the nascent universities however didn’t last long as cracks emerged regarding the political class’s approach to development and the role of the university and academics in that process. The re-establishment of the colonial universities anew as regional and national universities in the 1960s and 1970s, was accompanied by an admonition from the political leadership of a blanket expectation of academic freedom and institutional autonomy by the academics in the institutions (Dlamini, 2002; Crawford et al., 1967). Throughout the continent, the establishment of the new universities was accompanied by contradicting declarations from the Chancellors, who happened to be the presidents of the countries of the kind of universities and the nature of academic freedom expected. In Ghana, for example, Kwame Nkrumah, while addressing graduates on 24th 1963 noted:

We know that the objectives of a University cannot be achieved without scrupulous respect for academic freedom, for without academic freedom there can be no University ... Scholars must be free to pursue the truth and to publish the results of their researches without fear, for true scholarship fears nothing ... We know that without respect for academic freedom, in this sense, there can be no higher education worthy of the name, and, therefore, no intellectual progress, no flowering of the nation’s mind

But he noted:

We know that academic freedom can be perverted and even abused. It can also become a dangerous cloak for activities outside the academic interests and preoccupations of the community or of the University. Where this has happened, a grave disservice is done to everything for which knowledge and truth really stand. True academic freedom—the intellectual freedom of the University—is everything fully compatible service to the community; for the University is, and must always remain, a living thing and serving part of the community to which it belongs.

Quoted in Kwapong (1966: 546–547).
